From the preventive perspective, we can strengthen adolescents’ moral and social competences through digital game-based learning (DGBL). A positive youth development (PYD) electronic educational game is designed to attract and engage adolescents in examining and experimenting with the consequences of dishonest behavior in a non-threatening and manner.

This digital positive youth development (DPYD) game is designed to allow players to experience the natural consequences of being invited to engage in dishonest behaviors. Simulating the reality, players face temptations of breaking school rules as lured by peers

through new media via smartphone in a school setting and through online connections. The issues reflect a need for strengthening moral competence and media literacy.

In this game, honesty is regarded as good behaviors consistent with one's own inner consciousness, resulted from a full self-awareness which is not copied or being forced from outside. Players are given choices to conform or to refuse in different scenarios when the story develops. Players make choices that represent their perceptions of the importance of honesty and sincere confession as well as their willingness to conform to peer pressure. Players experience the consequence of their choices as the game continues. Moreover, it also introduces solutions when facing threats from classmates and simulation scenarios relating to forgiveness.

A Digital Game

The game, "The integrity crisis," was designed for Secondary 1 to 3 (Grades 7-9) students. The story develops in and outside of campus. It describes how the character handles interpersonal conflicts when her or his privacy is invaded by classmates. The story has different scenarios in which the player is required to make a choice from six responses representing various ways of handling the conflict. The story will end differently according to the players' choices. The game takes about 10 to 15 minutes to complete, depending on the reading ability and attitude of the player. Both the male and female versions are available.

The teaching material mainly explores the choice between friendship and honesty, emphasizing the importance of honest and sincere confessions, and it allows students to experience the consequences of dishonesty. Honesty is defined as behaving consistently with one's own inner consciousness, where one is fully self-aware, and the resulting behaviors are not copied nor being forced from the outside. In addition, it also allows students to decide on different solutions or reactions when facing threats from classmates, which highlights the issues of forgiveness. Both male and female versions are available.

Figure 1. An image captured from the screen of the game.

Figure 2. An image captured from the screen of the game.

Friendship is an important element in the lives of adolescents. When a teenager is asked by a friend to do inappropriate things, he or she may blindly follow in order to maintain the friendship and possibly making mistakes together. Hence, the choice between friendship and integrity is worthy of reflection and learning, which is the key message of this game.

OBJECTIVES OF THE GAME

The purposes of this game can be separated into three different aspects: cognitive, emotional, and behavioral. On the “cognitive” aspect, the game allows students to reflect on the choice between friendship and honesty. Is maintaining a friendship more important or confessing one’s faults with the possibility of putting a tear in the friendship? It helps students understand the necessity of a sincere confession. Confessing allows one or more parties to understand the full picture of the situation, which can clear out any misunderstandings and apologize, so all parties can analyze the situation rationally to work out the best solution. The game can also increase students’ awareness of the different ways of handling threats from classmates through the choices they personally make in the game, as well as the different options they can choose from. It is important to stress that students always have a choice, and the outcome of the situation changes according to their response.

On the “emotional” aspect, the game allows students to put themselves in the character’s shoes as if what they are experiencing is happening in real life. Students can change from understanding the victim’s plight, to caring for the victim, and to showing compassion for the victim’s pain and negative emotions. This enables students to feel pity, sympathy, and empathy respectively in those situations described above.

On the “behavioral” aspect, the game allows students to perform drills through different scenarios, to prepare them for real-life if similar situations were to arise and to find out what actions they would potentially take. This enables students to consciously practice honest behaviors, refuse to perform inappropriate behaviors, and take appropriate actions in the face of frauds or extortions. On top of that, they can also do good deeds for their friends, proactively admit one’s fault, and forgive a friend’s wrongdoings.

GAME DESIGN

The first level feedback provides general guidance on the incident based on students' choices during the early phase of the story (the player hesitates to follow a friend's idea of modifying a school notice) and toward the ending (10th, 11th, episodes where the character faces the unreasonable threat of the class representative). The second level feedback targets students' strategies in handling conflicts while the third level feedback shows the calculated scores of the 20 positive psychological constructs of the player. They are discussed in chapter 3.

Storyline

A classmate Bruce/Carol invites the player to forge a school notice together in order to skip participating in a two-day life planning camp and join other classmates for other leisure activities. The character hesitates at first but eventually joins the forgery and faces the risk to be punished for violations of school rules. The forgery is discovered by the class representative who later keeps asking for money to cover up. The theme of the game is related to how the player makes his/her decision when facing the pressures from the classmates in various scenarios as the story develops.

Tips for Instructors

Instructors need to familiarize themselves with the objectives, design, and storyline of the game. One of the key teaching points is making choices and maintaining one's integrity. Class discussion on how students make a choice and their sharing of the experiences could illicit interests for the topic. Discussions on following rules and do the right thing versus breaking rules to fulfill one's desires or wishes, act or remain silent when threatened, agreeing with friends to do mischievous things or follow one's conscience could, on one hand, stimulate students' discussion, and on the other hand, gives the instructors some ideas of what students have experienced in real lives regarding those issues. Instructors should be sensitive about students' disclosure of their personal experiences, which can cause upsetting emotions. Reminding students to respect one another's disclosure for the sake of learning from one another, and students should not tease or tell others what their classmates have said in the sharing.

RELATED TEACHING UNITS FOR THIS GAME

Prosocial involvement (PI), resilience (RE), moral (MC) and social competences (SC) are the core PYD constructs for this game. Anti-bullying (AB) is a major developmental issue. There are five related teaching units in the original and revamped program of the Project P.A.T.H.S. launched in 2006 and 2009 respectively – MC3.4 "The Stolen PIN," SC3.4/AB3.2 "Alien," PI1.2/AB1.2 "Behind the Mask of Bullying," RE1.3/AB1.3 "A Secret Book of

Bullying Prevention,” and PN2.4/AB2.1: “I can make a Difference.” The last two units will be presented in chapter 6 on the game to prevent bullying and cyberbullying. The concept maps of all teaching units can be accessed through the P.A.T.H.S. website <https://www.P.A.T.H.S..hk/en/>. Table 1 shows the three most relevant units which will be described in detail below.

Concept maps of all teaching units can be found in the special teaching units except for MC3.4, which are updated teaching units of the teaching materials of the Project P.A.T.H.S. This game and the other game “the Bullying Storm” share some of the teaching units under the theme of anti-bullying (AB). They are summarized in the following table. For all concept maps, please visit <http://www.cityu.edu.hk/ss/pltr/ty/new/en/enter.html> (Flash Player required).

Table 1. The three most relevant teaching units

Game	Issue	Construct(s)	Unit(s)
The Integrity Crisis	Honesty, isolation caused by bullying	Moral Competence (MC)	MC 3.4: “The Stolen PIN”
		Social Competence (SC)	SC3.4/AB3.2: “Alien”
		Prosocial Involvement (PI)	PI1.2/AB1.2: “Behind the mask of bullying”

Unit MC3.4 “The Stolen PIN”

Figure 3. The concept map of the teaching unit MC3.4.

Teaching Points

The construct for this unit is resilience (RE). In this unit, individuals understand that the interrelationship between honesty and credibility. The more honest one behaves, the more credible he or she is, vice versa. Individuals also realize that peers play an important role in influencing their behaviors of honesty and dishonesty, which indirectly affects their level of credibility as well. Lastly, they learn to suffer the consequences when performing actions of dishonesty.

Instructors should encourage individuals to be honest with others and find some good friends. Having friends with a positive and upright character, they would eventually develop these characteristics, such as being frank to people around themselves. In the face of issues on being dishonest, they are confident to face their faults and bravely bear the consequences.

Unit SC3.4/AB3.2 “Alien?”

Figure 4. The concept map of the teaching unit SC3.4/AB3.2.

Teaching Points

The construct for this unit is social competence (SC). Everyone is unique and we need to realize the difference between each other. Many factors contribute to those differences such as family background, appearance, lifestyle, personalities, and individual's thoughts and values. Thus, one should not tease or make fun of others because of those differences. Instead, we should try to understand the differences, and learn to tolerate and accept others as different from us. Instructors should focus on discussing the differences and what makes everyone unique with students.

We should encourage respect, understanding, and tolerance; and condemn discrimination, teasing behaviors, bullying incidents. There are lots of differences one can pick from their classmates such as behaviors, studies, and how one interacts with others, but we need to learn to respect and appreciate individual differences. When faced with bullies, one should be dispassionate when being teased and use a firm attitude to let the bully understand that individual differences are part of nature. We should never look down on others because of our differences. Instead, instructors should remind students that they can make a difference and influence others to take proper actions.

Unit PI1.2/AB1.2 “Behind the Mask of Bullying”

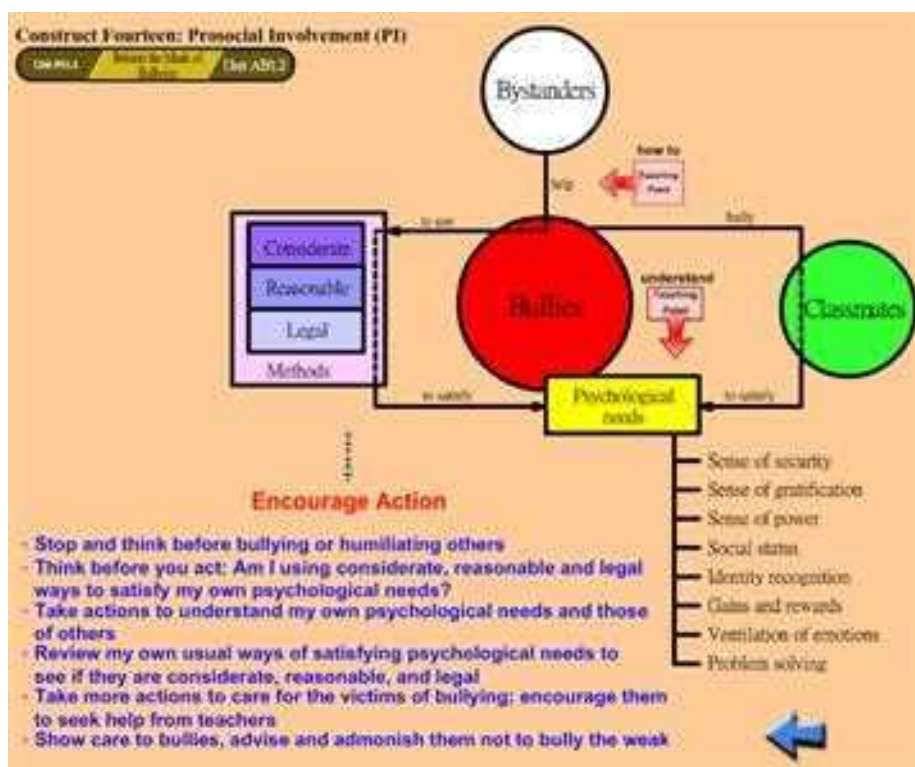

Figure 5. The concept map of the teaching unit PI1.2/AB1.2.

Teaching Points

The construct for this unit is prosocial involvement (PI). This unit explores the mindset of bullies in a bullying incident. Usually, bullies bully their classmates in order to satisfy their psychological needs, including having a sense of security, sense of gratification, sense of power, a higher social status, better recognition of identity, a favor of gains and rewards, ventilating their emotions, as well as solving their own problems. It's crucial for bullies to understand that their actions initially do not intend to hurt others, but it's a maladaptive approach in response to their inner issues. Besides, bystanders can help bullies by using considerate, responsible and legal methods to respond to their psychological needs. From time to time, bullies learn to express themselves in an appropriate and acceptable way.

Instructors should encourage individuals to think before performing bullying or humiliating actions, again stressing the use of considerate, responsible and legal measures to satisfy individuals' psychological needs. Moreover, concrete actions ought to be taken to understand the psychological needs of bullies and those of others, such as doing personal reflection and review on their interpersonal skills, caring for victims and bullies' inner needs, fostering help-seeking behaviors from trust-worthy people (e.g., teachers), advising and admonishing bullies not to bully the weak.

CONCLUSION

Everyone treasures friendship in our lives and students need to be careful when handling the relationship with friends. It is understandable that peer pressure is not easy to resist. During the adolescence stage, peer plays an elevated role and occupies a large proportion of their lives. Informed by the peer cluster theory, we come to figure out why many prevention and educational programs failed to compete with the youth's original environment, in which the norming influences of peer clusters eliminate the gainful learning experiences [22, 58-59]. This interactive game shows how peer influences challenge adolescents' honesty and integrity. The lively issues engender thought-provoking process; given appropriate time to think and experience the possibility of alternative decisions. They are real-life examples of viable solutions which are seldom available in their own peer interaction. The process of provision of proper guidance, coaching, and accurate information may be able to elevate certain alternatives way to counter-influence peer cluster pressure. It is hoped that participants could be well equipped and informed to choose wisely when faced with situations they have to make a choice, bearing in mind the importance of honesty and integrity.

USER FEEDBACK - PERSONAL REFLECTION

Below is the written feedback of a female aged 15 who studies in an international school in Shanghai, China. Parental consent to play the game and publish her views was obtained.

“After playing this game, I realized how difficult it might be to say no to friends. It is one case to disagree with what someone you dislike is doing, but it is much harder to say no to friends because you value their opinion of you. Additionally, after trying out different options for the ending, I also learned that how you choose to communicate with your friend will have a large impact on how long the friendship will last. If you really value a person’s integrity and loyalty, Carol’s betrayal of you may not mean that you want her as a friend. However, you can still try to keep things neutral and avoid an altercation or fight. Overall, this game/simulation also reinforced the idea that breaking the rules has consequences, but if the main ‘rule-breaking’ has happened already, consequences can be minimized by acting responsibly and contacting an adult when no previous strategies have worked.”

A 19-year old student studying at a college in the U.S. wrote:

“There was no option in the game to reject Bruce’s idea in early stages. Personally, I would have firmly said no. I believe the expectation was that it was very hard to say no to Bruce. I liked there were different endings, depending on how you resolved your disputes with Bruce. You would either be able to mend or destroy your relationship with Bruce. However, it should be emphasized that how to approach friendships and relationships are nuanced. There could be a middle ground between different options. There is no one right answer.”

DISCUSSION

The peer cluster theory has helped us understand the operationalization of peer influence and the pressure a favored peer cluster will have on youth’s non-conforming behaviors. Young people are prone to be influenced by peers. The theory sheds light on the understanding of why providing information alone is ineffective for treating adolescent misbehavior. For primary prevention, the learning gained from educational programs cannot withstand the peer influence engendering from their favor clusters. The complexity of many integrity issues and moral developmental examples of violation of school rules, like fraudulence and victimization, and having secondary deviance because of differential association and being further labeled are just many vivid challenges in adolescents’ daily life.

The game has several contributions. First, it provides knowledge and skills in handling peer pressure. Second, it offers choices that players can learn vicariously. Third, it creates chances of cooperative learning that encourages open discussion and support rather than competition and didactical communication. The game design may maximize the positive effects of the reciprocal relationship among peers which is the essence of secondary prevention.

Cooperative learning provides the quintessential way to counter-influence peer cluster pressure since the adult facilitator will remain neutral and distant, not providing the orthodox answer, nor responding with reckless comments. This facilitative stance may facilitate adolescents to seek their own answers from an active learning process. The other major contribution to cooperative learning is the notion of awaiting and motivating the readiness of adolescents. Adults often look for quick measures and are easily losing the patience to allow young people the time of contemplation, deliberation, and making fair decisions. This helps explain why the learning processes in sharing of ideas and viewpoints may help explore identity and encourage adolescents to exchange diversified interactions to curtail some risk factors for engaging in cyberbullying [60]. The elements among this gaming cooperative learning consists of considering individual accountability during challenging situations, face-to-face interaction (internet communication) to reveal one’s own decision making, positive

interdependence thinking through the empathetic reflection to the plight of others, and finally, the essential social skills acquisition, which will be crucial for moral decision making and integrity building [61, 62]. Applying these games in cooperative learning can make the gaming process a tool for engagement, initial diagnosis, reflective discussion, skills acquisitions to relate to peers in difficult situations where students are lured to engage in deviant behaviors [22].

Here a DPYD game is designed to enhance motivation and engagement in positive youth development. Whether or not it has a positive impact on the learning outcomes is of prime concern. Empirical evidence supports that playing serious educational games (SEGs) facilitates users to learn the content and boost knowledge acquisition [63]. Cheng and associates' study results are informative to science educators, game designers, instructional designers, and SEG advocates. The results offer empirical evidence that SEGs allow students to understand the confusing and difficult concepts of the human immune system in an easier way [57].

Even though some evidence supports the use of SEGs, there is still substantial controversy about the actual effectiveness [64]. SEGs help students gain procedural knowledge and facilitate a higher-level cognitive process [57]. They allow students to gain positive learning experiences that are useful, clear, attractive, interesting, and satisfying [57, 64]. Many scholars still believed that playfulness was negatively associated with the learning outcomes of users. The playfulness of SEGs can be a double-edged sword since excessive playfulness may generate some issues which instructors have to consider when using SEGs in facilitating student science's learning [57]. On the other hand, many scholars maintained that playfulness is one of the major attractions in motivating adolescents' participation [64-66] especially in serious issues such as morality in computer game learning.

Implications for Practice and/or Policy

As in many emerging methodologies in social science programs, many practical problems come up before answers can be provided. There is much to be discussed not just in the fun versus learning dichotomy. Experienced practitioners often think about how much games will contribute to intervention. Here comes the contention of active versus the laid-back style of game program facilitation. It is not appropriate to provide direct answers in the process of cooperative learning while a more carefree learning atmosphere might as well not be desirable for evaluating what the participants have learned in the process. Here we stand in the crossroad of pushing for a result or allowing participants to contemplate. In experiential learning, a concrete experience gained through the participation in a game can be used and tested in new scenarios, to verify and to apply in daily life [66]. Substantial follow up and facilitations by experienced practitioners are essential. Here comes the challenge of limited resources vs. the intensity of learning and growth. The most challenging situation is how to allow for the maturity of discussion in important value clarification issues such as cheating/lying, integrity, freedom, and liberty to help learners be better able to comprehend the desired educational targets while the facilitators might need to advocate for certain morality direction from the funders and donors.

The above discussions have implications on practice and policy to be implemented in serious game learning. The know-how of game program design should address the issue of balance fun to attract with the seriousness of the contents. For example, how to engage adolescents with the free spirit of discussion in a scenario of integrity is a matter of program design and process facilitation.

The multi-level of value self-examination of funders, designers, and practitioners are quintessential, as the serious computer game might have generated moral discussion and reflection to question the above stakeholders' position before adolescents come to re-examine theirs. If life integrity issue should go beyond cognition to practice, the application issue of game learning reserves more resources and energy to handle with. The second part of the evaluation of effectiveness should be focused on the impact of learning on daily life. This helps to answer the prime concern of the effectiveness of DPYD, not only for investigating the results but also for its impact on the life-changing capacity for participants.

ACKNOWLEDGMENTS

The design and production of the 7 digital games introduced in this special issue, the preparation of this work, and the Project P.A.T.H.S. were financially supported by *The Hong Kong Jockey Club Charities Trust*. Readers may request free copies for non-commercial purposes of these games by contacting Dr. TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This chapter is based with permission on a paper adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

ABSTRACT

This chapter presents a brief literature review on the issue of bullying and cyberbullying (BCB) among adolescents. It then introduces the project P.A.T.H.S. which sponsored the design and production of this digital positive youth development (DPYD) game to strengthen three positive youth development (PYD) constructs - social competence, moral competence, and pro-social norms among early adolescents. It then describes how it can be used to enhance media literacy to prevent BCB which are very often intermingled as a result of prevalent use of information and communication technology (ICT). A description on how to use the game in conjunction with related teaching units of the project P.A.T.H.S. for primary prevention is presented. Teaching points and tips of related units are also provided. To demonstrate the potential effectiveness, two young users – a 15-year-old female from China and a 21-year-old male

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

from the United States were invited to play the digital game and provide comments on the game design and perceived effectiveness. How the game can be used for secondary and tertiary prevention is also discussed.

INTRODUCTION

The availability and use of electronic devices, particularly mobile phones, has been exponentially growing over the years. This widespread behavioral change in excessive use on screens has given us a new online platform in exchanging instant information and connecting with people that we may or may not have known in life. Meanwhile, it has also created many issues that may have brought from offline to online, such as bullying, which is typically named as cyberbullying, electronic bullying, or internet bullying. Cyberbullying is among the most commonly exposed and unidentified risk for children and adolescents on the internet.

Over the years, scholars have proposed different approaches to tackle the issue of bullying. However, the problem of bullying has been worsening in the digital era. In 2018, it was found that 59% of the American youngsters experienced cyberbullying or harassment. In Britain, 54% of the teenagers aged 12-20 reported that they experienced bullying, while 33% of them cyberbullying [1]. A study conducted by the UNESCO [2] reflected that Hong Kong's cyber victimization is as serious as in western countries, proven by an overall victimization rate of 30.9% and a testing and blaming rate of 18.9%. These results correspond with the research by the Organization for Economic Co-operation and Development (OECD) in 2018 [3], which focused on the mental well-being of students aged 15. It is found that Hong Kong has the most serious bullying situation in schools. More than 32% of the respondents reported having experienced bullying from peers, which is more serious than Canada (20.3%), Taiwan (10.7%) and America (18.9%). On average, around one student in each class reported they were beaten or pushed several times in one month. Furthermore, one in three Primary 4 to Secondary 3 students experiences internet victimization [4]. These figures highlight the seriousness of the issue.

The impact of cyberbullying may affect a much larger number of people at a faster rate than bullying. The Hong Kong Family Welfare Society [4] found that one-third of the children and early adolescents in primary and secondary schools were victims of cyberbullying. Inadequate parental support and skills may undermine parents' role in protecting their children. In addition, parents working long hours may also compromise parent-child relationship. Research shows that the tendency of bullying cases decreases if students' relationship with their teachers is positive [3]. In contrast, if the victims receive limited support from classmates or teachers, they will have a higher tendency to become victims in cyberbullying [4]. These findings indicate the importance of bonding, a PYD construct which promotes positive interpersonal relationships, as an effective element to curb bullying.

There is a growing concern on the prevention of BCB, and an interest in the use of digital games to promote PYD among adolescents for successful adaptation to challenges they face in and out of school. This chapter discusses how to apply game-based learning (GBL) to tackle the BCB problems. We will also study how a newly-developed DPYD game can be effectively used as a preventive measure for BCB encountered by adolescents. In this chapter, we seek to:

- review briefly the literature on bullying and cyberbullying;
- outline the design of the digital game and its relationship with the project P.A.T.H.S.;
- provide users' review on the game to identify its strengths and weaknesses; and,
- discuss issues related to DPYD game for prevention of bullying and cyberbullying.

LITERATURE REVIEW

Cyberbullying in adolescence often comes in the form of voluntary and repeated assaults against a person through offensive emails or text messages, instant messaging, or inappropriate act on social networks/social media [5]. In a study of 4,477 elementary, middle, and high school students in Israel, the results revealed that approximately 30% of the participants experienced personal victimization from cyberbullying in their WhatsApp classmate groups [6]. Children and adolescents exposed to cyberbullying, whether as cyberbullies, cyber-victims, or both cyberbullies and cyber-victims, are strongly related to the use of social networking sites. The risk of victimization increases with the time spent online [7, 8].

Cyberbullying and Traditional Bullying

A major theme in the literature is the linkage between traditional bullying and cyberbullying. While adolescents mainly use the internet to maintain pre-existing friendships, some make close friendships online. Although there are legal and behavioral definitions of cyberbullying, some victims do not perceive all such behaviors as cyberbullying [9]. Moreover, they perceived aggression online and at school differently. Cyberbullying is generally perceived as less problematic than traditional bullying partly because the online environment lacks clearly established rules, physical presence, body language, authority figures, and formal reporting mechanisms [9].

Recent studies have identified the potential risks of cyberbullying in using social media platforms for children and youths. The insensitivity to information privacy threats will also increase the exposed risk [10]. Fogel and Nehmad [11] conducted a study on privacy concerns in the social network communities and found that on "Facebook" social media platform, 75% of the sample population have no restrictions on who viewed their profiles and about 10% showed their phone numbers and home addresses on their profiles publicly. Another study showed that some adolescents who are heavy social media users are less likely than their peers to be victims of cyberbullying and less likely to bully others [12]. The characteristics of cyberbully-victims and cyberbullies are different. Cyberbully-victims are typically similar to one another in that they have low self-control, offline aggression, low level of empathy, and heavy consumption of violent media [13, 14]. Media violence exposure was a risk factor leading to both cyberbullying and cyber-victimization [15].

Regarding the bystander effect in cyberbullying, adolescents' relationship with both the perpetrator and the target may affect whether they would intervene when witnessing cyberbullying. The relationship may also affect their ability to understand the context of the situation and the perceived severity of the effect of the incident on the victims [9, 16].

Impact of Cyberbullying on Victims

Cyberbullying poses severe threat to the overall wellbeing on cyber-victims in terms of their emotional and psychological health. Cyber-victimization in adolescents was found to be associated with greater internalizing problems, such as feelings of loneliness, anxiety, and poor psychosocial well-being [17]. Among the problems, cyber victimization and depression have the strongest relationship. It was reported that suicidality is also linked to victimization [18]. Moreover, the exposed risk on the use of multiple social media platforms had substantially put users at greater odds of having higher levels of both depression and anxiety symptoms [19, 20]. Primack and colleagues [19] argued that depression and anxiety symptoms may be related more to participation in multiple social media platforms than to the amount of time spent on social media. Plausible reasons include multitasking among platforms which may lead to poor cognitive and mental health outcomes [19, 21], difficulties in adjusting to unwritten rules, cultural assumptions, and idiosyncrasies of different platforms [19], and a higher risk of insensitive language being misinterpreted and magnified. All these could further aggravate the problem and lead to severe distress and even self-harm in extreme cases [22].

Age and Gender Differences

The high penetration rate of smartphone and the internet may facilitate wider age permeability of cyberbullying among children and adolescents. For gender differences, Festl and Quandt [23] found that females' cyberbullying involvement in both perpetration and victimization could be traced back to more intensive online social activities and a higher amount of online contact with strangers. For males, only higher exposure to antisocial media content predicted higher levels of victimization over time. Moreover, males were also found to be more likely to engage in sexual cyberbullying perpetration, yet females were more likely to engage in psychological cyberbullying perpetration [14]. This information is useful when designing DPYD games and one must consider potential players' age and gender and use gender-appropriate contents to yield the best outcomes.

Preventive Measures

There is an urgency for intervention for BCB through a holistic approach. Ttofi and Farrington's [24] meta-analytic review showed the positive impact of school-based anti-bullying programs with an overall 20-23% decrease in bullying and 17-20% reduction in victimization. A recent systematic review on prevention and intervention on cyberbullying among adolescents reported that the most frequently used intervention components include coping skills training, empathy training, parent education, and enhancement of communication and social skills [25]. Specifically, an intervention program with eleven sessions over a period of 3-month focusing on enhancement of emotional skills reduced victimization and assault. It also enhanced emotional perception and regulation skills and life satisfaction [26]. Recent efforts have been made in adopting program elements originally

designed for traditional bullying in dealing with cyberbullying [27]. Interestingly, programs focused at the school level were found to have the strongest effects against cyberbullying [28]. Slonje, Smith, and Erisen [29] also found evidence to support components, such as a whole-school anti-bullying policy, activities to promote awareness, curriculum-based and classroom intervention and prevention efforts, as well as support for victims from capable peers.

Issues regarding BCB are real challenges for human services and mental health professionals. It was evident that intervention strategies can be successful in reducing the problem, thus, more efforts should be put in prevention of the problem. Literature review supports a holistic approach to tackle the issues from the ecological perspective. Specific educational strategies are adopted to strengthen students' empathy and effective decision-making ability [30]. For example, the Project P.A.T.H.S. [31], which adopted a holistic PYD approach to enhance psychosocial competencies among early adolescents (Grades 7-9) through a universal school-based curriculum and a secondary prevention targeting students with greater psychosocial needs, was demonstrated to be effective in reducing risky behaviors [32-34]. The project, adopting 15 constructs identified as core components of PYD, has been recognized by the World Health Organization as an evidence-based program in one of the seven strategies for ending violence against children [35] and one of the three evidence-based programs for promoting life and social skills in adolescents [36].

A total of 120 30-minute curriculum units were designed with reference to 15 positive youth development constructs identified in the successful PYD programs [37]. Specifically, the Project P.A.T.H.S. developed seven units to help students enhance five PYD constructs which include moral and social competencies, resilience, prosocial norms, and prosocial involvement. These units aim to promote general awareness on bullying, space for self-reflection and opportunities to rehearse new behavior. Students learn how BCB harm themselves and others, and they practice skills to help protect themselves when being bullied. They also learn bystanders' role and learn skills to be responsible bystanders in school bullying and cyberbullying [38].

A Digital Game for the Project P.A.T.H.S.

The game, "The bullying storm," was designed for Secondary 1 to 3 (Grades 7-9) students. The story mainly focuses on the theme of bullying. It is relatively simple, and it develops according to the choices of the player. Both male and female versions are available. Learning in a safe environment is one of the basic rights of students. However, bullying occurs from time to time on school campus or outside, where victims often suffer from physical and mental harm. Therefore, learning to adhere to personal principles, protecting oneself properly and seeking assistance actively are important issues when facing bullying. The game takes about 10 to 15 minutes to complete, depending on the reading ability and attitude of the player.

Figure 1. An image captured from the game (female version) illustrating choices available.

Figure 2. An image captured from the game (male version) illustrating choices available.

OBJECTIVES OF THE GAME

The game targets three different aspects: cognitive, emotional, and behavioral. On the “cognitive” aspect, students can develop a deeper understanding of school bullying, the need to adhere to important personal principles, the need to seek assistance actively if necessary, and the various ways of dealing with different types of bullying.

On the “emotional” aspect, the game allows students to put themselves in the character’s shoes as if they were experiencing the issues in real life. Students can change from understanding the victim’s plight to caring for the victim and showing compassion for the

victim's pain and negative emotions. This enables the player to feel pity, sympathy, and empathy respectively in those situations described above.

On the “behavioral” aspect, students can learn to take appropriate action to deal with interpersonal conflicts, seek help proactively from teachers or good friends in the face of bullying, reduce behaviors that escalate bullying incidents, and prevent bullying from worsening.

This game makes use of a story line and provides various scenarios for users to choose as the story develops. In each scenario, users are given six different responses to choose from, and it will affect the development of the story accordingly. Corresponding feedback and guidance on three aspects will be provided based on user's responses to all scenarios at the end of the game. First, comments according to the end of the story will be shown. Second, based on students' responses, their patterns of conflict resolution strategies in terms of communication mode, including competing, avoiding, accommodating, compromising, and collaborating will be presented in the form of percentage. Third, the relative strengths on each of the twenty positive psychological constructs in percentage format based on the choices will be shown. They are discussed in chapter 3.

Game Design

The story develops in the school campus, and it describes how the character handles bullying. The story has different scenarios in which the player is required to make a choice from six different responses representing various ways of handling the bullying. The first level feedback is based on the ending (the 11th episodes when the character is facing the bullying incident), and there will be guidance provided according to the user's choices. The second level feedback targets users' strategies in handling conflicts. The third level feedback shows the calculated scores of the twenty positive psychological constructs of the player.

Storyline

A student, Bruce/Carol (depending on the gender of the character), who is an active key figure in class. Bruce/Carol is the captain and coach of the basketball team and he/she plays the role of a bully in the story. He/She has many followers, but he/she often bullies others and abuses his/her power. Unfortunately, the player becomes his/her target. Facing the mockery and exclusion of the classmates, how will the player escape from this predicament?

Tips for Instructors

Instructors need to familiarize themselves with the story line, the teaching points and the plot of the game. They can remind students to pay special attention to the issues surrounding bullying and being threatened by others throughout the game. There are plenty of places in the game where instructors can pause the game/game demonstration to dig deeper into issues with students in the form of class or small group discussion if time allows. Instructors can

remind students to apply the knowledge of making choices in the previous game to the scenarios when facing bullying - Bruce/Carol snatches the player's pen, which is the player's birthday present or when Bruce/Carol wants the player to take a picture of a completed assignment and send it to him/her. Having the class to discuss what they will do in a few scenarios can motivate students to continue with the game on their own. More importantly, the class may apply knowledge and skills which include self-awareness, moral decision making, perspective-taking, empathetic understanding, effective communication, and relationship building and maintenance in real life situations.

Related Teaching Units for This Game

Anti-bullying (AB) and internet use (IT) are two of the five developmental issues of the revamped program of the Project P.A.T.H.S. launched in 2009. There are seven teaching units on the theme of anti-bullying. Among them, five are directly related to the game which were designed as intervention to address the issues of BCB. They are AB1.1 (Incidents of Bullying), AB1.2 (Behind the Mask of Bullying), AB1.3 (A Secret Book of Bullying Prevention), AB2.1 (I Can Make a Difference), AB2.2 (Make a Smart Move), AB3.1 (Online Buddies), AB3.2 (Alien?), and MC3.4 (The Digital Age). Table 1 shows the four most relevant units which will be described in detail.

Table 1. The four most relevant teaching units

Game	Issue	Construct(s)	Unit(s)
The Bullying Storm	Bullying, cyberbullying	Resilience (RE)	RE1.3/AB1.3: "A Secret Book of Bullying Prevention"
		Resilience (RE)	RE1.4/AB1.1: "Incidents of Bullying"
		Prosocial Norms (PN)	PN2.4/AB2.1: "I can make a Difference"
		Moral Competence (MC)	MC2.2/AB2.2: "Make a Smart Move"

Unit RE1.3/AB1.3 'A Secret Book of Bullying Prevention'

The construct for this unit is resilience (RE). When faced with bullying, students can choose different ways to respond in the situation. Staying calm can be helpful, and they should never use the method of "an eye for an eye" because it would only make things worse as it causes more harm to more people. Instructors can remind students to weigh the circumstances and make wise decisions. Instructors should also encourage students to seek help from teachers or social workers and not to provoke the bully. Responding with the "I" message approach in the face of bullying can be effective to bring across the message. It conveys the feeling of the speaker and explains the needs of the speaker, and it does not imply any criticism of others.

Instructors can help students understand the characteristics of bullies fully and deeply to avoid intensifying or further provoking the act of bullying. These methods can help students

to stop others from bullying them, and they learn to stand their ground. Instructors should discuss the methods with students and encourage them to learn these methods by heart to stop others from bullying them.

Students should never tolerate any bullying behaviors. Instructors can remind students to stay calm when being bullied or in the face of bullying. Students can find suitable ways to respond and use the methods they have learned from this unit. Instructors should also remind students that the approach to tackling bullying varies according to the environment, situation, type of bullying, and reactions of the bullies. Students should consider the environment and make wise decisions accordingly.

The following concept map shows the contents and teaching points of the unit. Further pointers are provided for instructors to encourage students to take appropriate actions.

Figure 3. The concept map of Unit RE1.3/AB1.3 'A secret book of bullying prevention.'

UNIT RE1.4/AB1.1 'INCIDENTS OF BULLYING'

The PYD construct for this unit is resilience (RE). There are many forms and ways of bullying. They can be physical, verbal, social or extortive. Bullying are often physical or psychological attacks involving a wide disparity in strength between the bully and the victim, and it is often done repeatedly. Victims who are bullied most suffer from negative consequences psychologically, and/or physically, which can have a short term, long term, or even a permanent effect on the victims.

Instructors are encouraged to analyze the thoughts of bullying and explore the negative consequences on victims. Also, we should encourage students to stop all bullying behaviors and not to provoke bullying behaviors. Students should learn to be wise and brave rescuers, but they should ensure one's safety before seeking help from teachers when facing bullying. They should treat others with kindness and understanding and participate in activities to build a harmonious campus. The following concept map shows the contents and teaching points of the unit. Further pointers are provided for the instructor to encourage and guide students to take appropriate actions.

Figure 4. Concept map of Unit RE1.4/AB1.1 ‘Incidents of bullying.’

UNIT PN2.4/AB2.1 'I CAN MAKE A DIFFERENCE'

In the face of a bullying event, one should consider some personal factors, such as responsibility, safety, and benefits in order to decide if one should intervene in the midst of a bullying incident. The more people take the stance of a bystander, the less the likelihood of a

person in the bystander group to take action. In a school bullying incident, most students are bystanders. Instructors should discuss the bystander effect with students and how the attitudes and responses of the bystanders affect the bullying incident.

Instructors, therefore, can encourage students to reflect on one's actions and responses when witnessing a bullying incident, such as seeking help from teachers immediately when it is safe to do so. Also, if possible and under safe circumstances, students can provide help to victims and encourage others to provide help and reduce the "bystander effect."

Figure 5. Concept map of Unit PN2.4/AB2.1 'I can make a difference.'

Besides, instructors can make use of other methods, such as role play and group discussion to help students understand the feelings of the victims. They can guide students to reflect on circumstances, such as if other people turn a blind eye when they are the victims, and how they will feel if others watch with folding arms and do not offer any help. When students suspect any bullying incidents, they should try to dissuade others from associating with them. The bottom line is that bullying should never be tolerated or encouraged.

Bullying violates the rights of others and no one deserves to be bullied. Schools should help students acquire proper values and skills so that they become alert of such incidents and know what actions to take when they encounter any bullying incidents.

Figure 5 shows the concept map.

UNIT MC2.2/AB2.2 ‘MAKE A SMART MOVE’

There are personal factors for us to consider, such as power, safety, and friendship when we have to decide what to do in times of bullying. We can intervene wisely, choose to neglect, be a bystander or instigate when faced with bullying. Instructors can discuss some of the personal factors with students and let them share with one another what those factors look like for them.

To conclude, instructors should encourage students to avoid direct conflicts with bullies and their allies. Students should ally themselves with reliable friends and learn to be very discreet in reporting any bullying to teachers in details. Also, instructors need to remind students to keep the matter confidential after reporting the incident to teachers. Students can befriend victims of bullying, show their support, concern and encourage them to stay strong, to seek help from teachers or social workers when being bullied. We all have to learn to take our stance: “Say no to bully and stay strong in the face of evil.”

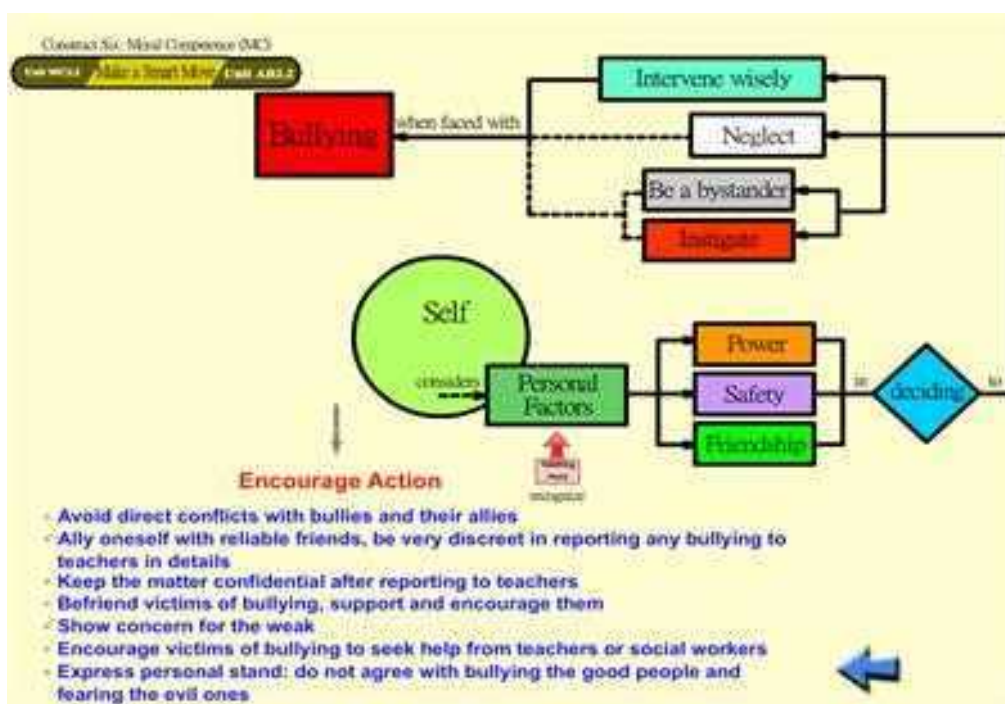

Figure 6. Concept map of Unit MC2.2/AB2.2 “Make a smart move.”

UNIT MC 3.4/AB 3.1 ‘ONLINE BUDDIES’

Some people use cyberbullying to humiliate, threaten and harass others. In the process, it always causes harm to the victims psychologically and mentally in their daily life. Instructors should discuss with students how to distinguish right from wrong when faced with cyberbullying incidents. There is always the option of reporting the incident to teachers or

social workers. More importantly, students should be reminded to stay firm and refuse to participate in any cyberbullying activities.

Instructors should encourage students not to disseminate anything that is not in accordance with facts to avoid hurting others. Students should not be an instigator and never gather others to participate in cyberbullying. They should advise others who participate in cyberbullying to stop their bullying behaviors. Students should not take revenge for others who are being bullied, but immediately seek help from teachers and social workers and maintain an objective and neutral attitude in handling information on the internet.

Figure 7. Unit MC 3.4/AB 3.1 'Online buddies.'

CONCLUSION

The teaching materials will arouse students' attention as bullying is a common phenomenon on and off campus. Most students have experienced being one of the roles as the bully, the victim or the bystander, and it is not difficult to recall what those scenes are like and how they felt. Instructors are in a good position to bring out the importance of choice, and

how different responses can lead to a more desirable and fair outcome to all parties. It does not help by avoiding, arguing or fighting with the bully, and students need to take actions, such as seeking help from social workers or discipline masters when bullying incidents occur.

User Feedback -- Personal Reflection

Below is the personal reflection of a female aged 15 who attends an international school in Shanghai, China. Parental consent to play the digital game and publish her own views were obtained. She wrote: “What I learned from this game was that there are many strategies for dealing with bullies in a class. A lot of responses to a bully will probably be related to how you feel and your personality type. For example, if you are a naturally shy person, when a popular girl like Carol bullies you, you may feel embarrassed and be more inclined to just ignore the problem at hand. This usually does not do anything to stop the bully from making fun of you; not speaking up for yourself may even make the situation worse. On the other hand, if you get angry too quickly and your responses are too harsh, the situation may also escalate quickly and end with punishments for everyone involved. Most of the more “successful” answer choices seemed to be answers where the narrator character was open about feelings and wanting change.”

A young adult man aged 19 studying in a college in the United States wrote:

“This game conveys the message that if you are getting bullied and do not respond, the problem does not necessarily go away. You have to respond to it and stand for yourself. However, I am not sure that it is necessarily true. Every situation is different. Sometimes, it is necessary to escalate things, and punishments for everyone are the most beneficial solution. Maybe it should still be stressed that every situation is different. There is no single right way, just do not end up bullying others as well because that will make you a bully too.”

DISCUSSION

BCB are complicated issues that require prevention at primary, secondary, and tertiary levels. A significant number of students are victims; some are intentional or unintentional bullies while many who have witnessed BCB remain to be bystanders. The high prevalence rate justifies continuous and concerted efforts in primary prevention for all to enhance students’ empathy, knowledge, and skills to handle the problems. This chapter attempts to contribute to the development of knowledge and practice of prevention of BCB through the development of a DPYD game, which can be used together with relevant PYD curriculum units, which are the foundation of the evidence-based program – the Project P.A.T.H.S. [32, 35, 36]. Qualitative evaluation comments from two users provide initial but encouraging support to the potentials of the game in helping adolescents. There are several issues that deserve attention.

First, there is a growing interest in the use of GBL [39] and gamification [40] in education and prevention of adolescent issues. The availability of a DPYD game presented in the context of on-and-off-line relationship targeting on BCB serves as an electronic resource for enhancing some specific PYD constructs which include moral competence, resilience, and prosocial norms. The game is intended to enable players for successful adaptations to

challenges in and out of school. With the generous support from the funding body, the digital game can be used with only little to no cost. It is hoped that a wide adoption of the game may contribute to a further reduction of the problem worldwide.

Second, the design of this DPYD game is based on theories of BCB as well as GBL. School social workers who work with secondary school students were consulted during the design stage. Their frontline experiences were adopted to develop the storyline. By adopting game elements, such as curiosity, attractiveness, different story endings for different choices, immediate and extensive feedback, the game has an attractive outlook. Following different storylines in the game, players' curiosity will be sustained. Different choices allow players to experience different endings and thus, obtain different feedbacks. The design can serve the functions of maintaining players' engagement and encouraging their repetitive use which will enhance the achievement of intended learning outcomes. Moreover, the use of cartoons/illustrations can help reduce the cultural barrier. The availability of gender-specific versions of the game may also increase the attractiveness and reduce the possible gender-bias problem.

Third, to prevent BCB, students need to learn knowledge and skills, such as self-awareness, moral decision making, perspective-taking, empathetic understanding, effective communication, personal reflection, and relationship building and maintenance. These outcomes can be achieved through conscientious discussions facilitated by well-informed instructors. This chapter illustrates how a well-designed, evidence-based prevention program helps reduce multiple forms of BCB and echoes the argument that there is no need for specific programs for different forms of BCB [41]. Recent research supports the development of empathetic understanding through digital games [42] and in-game empathy can predict interest in learning more about the game topic [43]. Providing information alone is not effective for preventive interventions [44]. In prevention of BCB, provision of legal knowledge and information on consequences for stakeholders do not change their attitude and behavior. Even though adolescents possess the knowledge and self-efficacy in not engaging in BCB behaviors, many victims may engage in cyberbullying for the sake of retaliation.

This chapter has several "practice" implications. The first implication is that this DPYD game could serve as a supplementary teaching and learning strategy in order to produce the best possible results in prevention. The literature supports offering school-based programs [24].

From the ecological perspective, an effective preventive program must reach all groups involved. A primary prevention program targeting all stakeholders is more likely to be effective. It may be practical for schools to implement primary prevention program for all students. The DPYD game can reach all students. With the support and guidance from instructors, students may become self-motivated learners.

The second implication is that schools can provide ongoing support for students with greater psychosocial needs and victims [45]. When most students are highly aware of the issues through a universal program and constructive ways of handling BCB incidents are introduced to all students, including victims, bullies, and bystanders, the dynamics and the processes of BCB are changed according to systems theory.

The third practice implication is for the helping professionals to use the game for secondary prevention. When most students are aware of the issues and ways to tackle the problem after playing the game, asking victims about their experiences in an open manner may become easier because the story in the game resembles their own experiences which may

be difficult for some to describe clearly. It may be easier for the helping professionals to build a working relationship with bullies, victims, or bystanders when they start by sharing and discussing similar matters albeit different perceptions. The issue of how to make good use of the DPYD game is important. The game is designed for primary prevention. It can be used for secondary prevention. It may be valuable for the helping professions, such as social workers, psychologists, mental health professionals to use the game for engagement, initial assessment, and discussion on the foci of intervention for individual intervention and for restorative and peer mediation on interpersonal conflicts between bullies-victims [46]. Although the digital game does not keep any personal data, with client consent, the use of print-screen function can facilitate the intervention process.

The fourth implication is on the implementation of evidence-based programs. Literature on the quality of program implementation supports the adoption of the 5 “P”s model which includes policy, people, program, process, and place [47, 48]. As a primary prevention effort to reduce BCB among adolescents, the Project P.A.T.H.S. is an evidence-informed and school-based program. Although the program aims at promoting holistic development, there is evidence to support that participants are better prepared to meet various challenges in their paths to adulthood [32, 35, 36]. Apart from the program and place aspects, the Project provided training to over 7,000 teachers and social workers to support the implementation of the program to promote PYD. Moreover, since the Project was supported by the Education Bureau and the Social Welfare Department, the policy aspect received proper support at the central and local levels. Furthermore, an average high rate of over 90% of adherence to the original design was recorded [49]. The adoption of the 5-P model explains partly why the program succeeded. The design and development of DPYD game serves as a supporting and reinforcement electronic learning resource to further enhance the effect of prevention.

The fifth implication is related to cultural issue. The attitude of adults in engaging adolescents’ participation in prevention and intervention to find a quick fix of BCB could be a challenge. It is particularly relevant to Asian societies in which authoritarianism still prevails. Joining in a game with real-life situations is much easier for adolescents to engage in non-threatening discussions and develop reflective thinking. Game-based learning facilitates in a dialogue among stakeholders without the guise of intolerance, exclusion, and rigidity. In a digital era, realizing youth’s potentials in shared leadership to create thoughtful, peaceful and inclusive interactive relationships are more viable than right or wrong responses to the legal and policy challenge of the daunting BCB issues [50].

ACKNOWLEDGMENTS

The design and production of the 7 digital games introduced in this special issue, the preparation of this work, and the Project P.A.T.H.S. were financially supported by The Hong Kong Jockey Club Charities Trust. Readers may request free copies for non-commercial purposes of these games by contacting Dr. TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This chapter is based with permission on a paper adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

ABSTRACT

The purpose of this chapter is to describe a newly developed digital positive youth development (PYD) game and discuss its effectiveness in understanding and reducing gender stereotypes and biases among junior secondary school students. The game, “male and female dichotomy,” allows students to explore gender stereotypes on “appearance,” “behavior,” “occupation,” and “traits” (ABOT) based on Deaux and Lewis’ gender stereotyping model. The design of the game is described after a review of relevant literature. The game guides students to examine the social demands and expectations of men and women in today’s world, and it enables them to reflect on how gender norms and their perceived gender stereotypes affect their perception on both genders. The game has been piloted in secondary schools in Hong Kong and is available free of charge upon request for non-commercial purposes. Two users who study in Shanghai and the United States were invited to review the game. Initial findings revealed that the section on “occupation” and “traits” were beneficial in the learning process, and the users became more aware of their gender biases. More research is needed to investigate the effectiveness of electronic game-based learning (GBL) in reducing gender stereotypes and biases among children and early adolescents.

INTRODUCTION

The problem of gender bias is global. Gender bias affects people in academics, career choices, and mixed-gender relationships, and to certain extent personalities. According to the ISSP Research group, women from more than 20 countries have reported issues of the family posing a challenge for their careers and women reported a higher level of family interference with work than men [1, 2]. The formation of gender identity starts at an early age. A study in Hong Kong suggested that boys prefer masculine toys while girls prefer feminine ones. Thus, this shapes children into certain personalities in that girls are found to be more empathic and less aggressive [3]. Furthermore, the awareness of a person's gender can harm his/her relationship with the opposite sex. Single-sex schooling is practiced in some schools. Wong, Shi, and Chen [4] suggested that single-sex school students are more prone to having mixed-gender anxiety and less mixed-sex friendship. As gender bias is a global issue, it is crucial to investigate this problem in search of prevention and intervention plans.

LITERATURE REVIEW

Gender stereotype is defined as the social standard perception of how males and females should think and behave in different situations [5]. Traditionally, men and women were assumed to be responsible for particular roles, appropriate behaviors, and duties in society. The social-political-economic-cultural opportunities for women in most cultures have been restricted, even though the situation has been improved noticeably nowadays in some economically advanced societies [6]. Furthermore, sometimes women are highly involved in the labor market. At the same time, they are still very often the major carer at home in most societies. Yet, the dual role of women has led to conflicts and concerns [7]. Caring for children and doing household chores are tasks usually taken up by working women. The notion of gender role difference, the practice of dual role, and the societal norms may have reinforced the stereotypical concept and the dual role. More importantly, this stereotype is found in children and adolescents in one way or another.

Gender Differences in Activities and Games

A study in Australia reported that teenage boys prefer spending time in physical activities or video games, whereas teenage girls rather spend their time on social activities, studying and household chores [8]. In fact, gender role learning starts at an early age, and this process continues in children's development [9]. Children can differentiate gender differences by 18 months old through their ability in associating gender-stereotyped toys (girls with dolls and boys with toy trucks) [10]. By the end of childhood, those who have a stronger gender identity reported to have pressure to conform to their gender role [11]. To behave according to the gender identity becomes a norm.

The Formation of Gender Stereotype

The development of gender stereotype involves children's interpretation of the information in their surrounding sociocultural environment. Based on this process, they form a representation of gender called "gender schema" [12]. A schema is a cognitive structure that guides an individual's perception through an association network [13]. The gender schema theory proposed that gender schema contributes to sex typing by individuals due to the readiness of processing information based on the sex-linked associations [13]. Ultimately, sex typing turns into a standard guide for one's perception and behavior, which also influences the concept of self-identity [12]. Self-identity is inseparable with gender as identity is the adoption of specific traits or groups [14]. By identifying the self with female or male, this identity becomes part of the self that increases the motivation to behave similarly to the identified group, attention to information of their own sex, and increases one's own interests in the activities that belong to one's own sex group [15].

The formation of gender stereotypes is complex and often derives from the sociocultural environment and cognitive development. According to social learning theory, people learn from observing others' behaviors and their consequences to avoid negative outcomes and gain benefits [16]. Leaper and Farkas [12] suggested that the development of gender identity involves four distinguished processes including the 1) social-structural process, 2) social-interactive process, 3) cognitive-motivational processes and 4) biological process. The social-structural process is the perspective on gender roles in society; the social-interactive process refers to the experience children interacting with others such as parents and peers; the cognitive-motivational process helps shape children's perception and interpretation on the world, usually related to self-esteem and self-identification; and finally, the biological process that children recognize from the physical differences with their opposite sex.

Media Influence

As part of socialization agents, mass media shape gender stereotype as they are the major source for children and adolescents to acquire an enormous amount of gender information. Even products for preschoolers are embedded with gender-specific messages such as bedsheets, furniture, toys and clothes [17]. The marketing of products for young children is also specific to gender, creating a differentiation between boys and girls [18]. Young children utilize the information they learn from popular culture and media to shape the way they dress, talk and play [19]. For example, media has been portraying females as a subordinate figure such as associating women with housewives and homemakers [20] and promoting a specific body shape [21]. With the constant exposure of this in-balanced or even biased information, adolescents form their perception of gender.

Parental Influence

Parents and significant others play a crucial role in the development of gender stereotype. Parents influence their child's perception of gender identity when they reinforce or discourage

certain behavior in play [18]. For instance, fathers react negatively to their children's cross-gendered behavior, particularly with their sons [22]. From that, children develop their gender identity on how they should behave according to their genders. Parents' contributions to their children's gender stereotype continue to the adolescence period [23]. A study showed that parents' distorted perception of their children's ability and interest based on gender stereotype affect children's performance in gender-role stereotypical activities such as sports and mathematics [24].

Peer Influence

Peer influence is powerful in adolescent development [25]. According to social identity theory, people naturally seek positive identification with social groups [26]. Adolescents learn to avoid behaviors that are inconsistent with their social group. Friends contribute to gender stereotype via peer pressure on how they interact with their friends. Children are aware of cross-gender behavior. For example, boys find their peers who display feminine behaviors and qualities less acceptable [27]. Boiché and colleagues [28] have proven that adolescents' sports performance, especially in girls, depends on their social environment. Moreover, if girls perceive sports-gender stereotype in their social environment, they are likely to drop out from physical activities.

To summarize, young children start to form their gender stereotypes while they are actively searching for gender cues in their environment [15]. Young children demonstrate their gender-stereotypical behavior through play [18]. For example, girls are likely to select family roles while boys prefer action-oriented roles in dramatic play [29].

Effects of Gender Stereotype

During adolescence, the effects of gender stereotype extend to appearance, behavior and personality traits. Young boys and girls have a certain perception of how men and women should look like. One interesting finding is that both boys and girls hold a perception bias in women's body size, underestimating the average body size of women with a slim-female thin ideal [30]. Such a perception is encouraged through advertisements in mass media promoting slim females, resulting in a decrease in body satisfaction and self-esteem in young girls [21]. In terms of behavior, young males are associated with verbal and physical aggression [31], a tendency to be engaged in risky behaviors [32], and a tendency to risk driving as the characteristic of risk-taking is associated with masculinity [33]. Moreover, girls show a less risk taking and more self-less characteristic compared to boys [6]. Females are also perceived to score higher in certain personality traits such as openness, conscientiousness, and agreeableness [34], while males are associated with instrumental traits including aggressiveness and competitiveness [35].

Consequences

Gender stereotyping does not only affect adolescent academic performance but also in physical activities and occupational choices. Numerous studies confirmed its effect on academic performance, in particular, mathematics. Research showed that adolescent girls are less likely to participate in a mathematic task under competition circumstances, while no gender difference is observed in verbal tasks [6]. In addition, it is found that girls perceive themselves to have better literacy ability, while they rated the boys lower in literacy [36]. Girls also feel less comfort and a sense of belonging to computer science due to the negative stereotypical concerns [37]. In terms of physical health, a study showed that adolescents are likely to hold stronger sports gender stereotype if they perceive their social environment to do so [28]. Additionally, personal endorsement of stereotypes can lead to dropout behavior when adolescents' perceived gender plays a significant role in the success of playing a certain type of sports [28]. In fact, boys adopt such a stereotype. They are more likely to participate in invasion game and reported invasive ball games to be enjoyable, while girls prefer to be a bystander and take an observer role, demonstrating gender differences in physical education [38]. Exercise is beneficial to young people's cognitive development [39] and reduces depressive symptoms [40]. With girls being less physically active due to the stereotypical effect, it could adversely affect their mental health.

While occupation aspiration will develop in children at an early age [41], early gender bias in occupational choice has been observed in boys that they tend to pursue a traditionally male career [42]. Adolescent boys usually have a science and mathematics career aspiration, especially if their male peers also hold the same career aspiration [43]. When asking both young boys and girls about their expectations on future occupation, young girls reported to value helping people, whereas boys preferred science-related jobs and valued variables such as becoming famous, earning lots of money and controlling others [44]. Interestingly, female adolescents exhibit struggles between their commitment to their future family and their future careers. Their career aspiration is also associated with their mother's occupation [45] and they tend to select a career that matches with their gender role [44].

Apart from affecting academic performance, limiting the choices of physical activities and occupation, gender stereotyping could have more severe consequences such as peer victimization which include physical, verbal, and relational aggression [46], social exclusion, and social isolation [47] for both genders. They can lead to a devastating outcome if a child was isolated or excluded from his/her social group because of exhibiting behaviors deviated from the gender norms. Interestingly, there has been little research that specifically examines the impact of gender stereotyping that focuses on how children think about the issue - what they understand about gender stereotyping and the consequences that bring forth by it [48].

Deaux and Lewis [1] identified a gender stereotyping model with four components to explain how people differentiate males from females, including physical appearance, traits, behaviors, and occupations. The model posits that information about physical features seems to be in the central position which strongly affects judgments about the other three components whereas the other three components affect one another mutually. Moreover, stereotyping is a cognitive process which is a necessary antecedent for a negative evaluation of any individuals or groups. As an attitude, prejudice is a necessary condition for discrimination behaviors.

PREVENTION STRATEGIES

Andreoletti, Leszczynski and Disch's [49] study on compound stereotypes (gender, race, age) suggested that gender stereotypes about agency and communion tend to remain across the life span and that people usually hold a unique stereotypical belief based on multiple social categories. For prevention, work should start as early as possible. Children's potentials and development are limited by gender stereotype and sexism [18].

Awareness and Reflection

To facilitate positive development in adolescents, it is important for adolescents to recognize and to be aware of gender stereotype in order to reflect on their own perception and behavior.

Role-Model and Workshops

One possible way is to provide a role model that overcomes gender-stereotype barriers [50]. Alternatively, educational workshops on gender stereotypes with teacher participation are found to be effective to facilitate students to make less gender bias decisions and behavior [51]. Given that, we expect teacher's involvement in the learning process as a moderator and guidance.

Classification and Game-Based Learning

Classification training has been shown in research to be helpful to resist gender stereotype information in young people [52]. The newly developed game adopts this idea with a final product of classification game highlighting the gender stereotype perception. We aim to help players identify gender stereotypes in order to reduce them.

Video games have been proved to have educational value, especially in this modern age where computer and video games thrive [53]. Students are more engaged when they learn from playing video games [54]. However, Weber and Custer's study [55] suggested that digital game-based learning (DGBL) might be more suitable for middle school students compared to high school students partly because middle school students showed a keen interest in contemporary technological learning activities and they may have less been exposed to such learning experiences. Thus, this supports why the digital games are specifically designed for middle school age students who start to develop their gender identity at this stage of their development with an aim to minimize the effect of gender stereotype.

DESIGN OF THE GAME

It is inevitable that we experienced a certain degree of social indoctrinations such as different views on women and men, and their respective demands and expectations from society when we grow up. In modern societies, many traditional gender roles or images have changed. For example, the number of husbands taking care of household chores has been increasing. Can we maintain an open attitude? Respect and acceptance are important elements of gender issues. Students may have already had their unique opinion on both genders growing up in their family, community and social environment. They might have a set of criteria regarding gender roles, which have been deep-rooted in their minds. To intervene, the game enables students to explore gender stereotypes on “appearance,” “behavior,” “occupation” and “traits” (ABOT). The aim is to examine the perception of gender stereotypes in contemporary society. It guides students to examine the social demands and expectations of men and women in today’s world. It enables them to reflect on those perceived gender stereotypes, and how they affect their personal perceptions of both genders.

This game targets participants of Secondary 3 level, the equivalent of Grade 8 in North America. There are four sections of the game to choose from, and instructors can choose selectively according to the needs of the students. Games range from 15-minute long to about half an hour.

Figure 1. The front page of the game.

Game Objectives

The objectives of this game can be separated into three different aspects: cognitive, emotional, and behavioral. On the “cognitive” aspect, students can develop a deeper understanding of their own gender stereotypes and biases in ABOT. On the “emotional” aspect, students can enhance their acceptance of the opposite gender in the four areas. On the “behavioral” aspect, students can reduce discrimination against people with a distinctive gender profile, and get along harmoniously with the opposite gender as a result of an increased acceptance level.

The games are designed for students to understand gender stereotypes as well as their views and values on gender roles. Besides, students can learn and understand how stereotyping affects career decisions and reflect on the importance of gender equality.

Teaching and Learning Method

Through the use of gender stereotype awareness games, feedback and guidance are provided for students according to their responses to help them reduce gender stereotypes and biases. Besides, instructors can make use of the supplementary teaching materials and encourage small group and class discussion on the topic of gender. Ideas of “Male Superiority, Female Inferiority” and “Men Focus on the Outside World, Women Focus on the Home” and their respective impacts on our society can be used for discussion to help students understand the traditional views on the two genders and the reasons behind those thoughts. Through the exploration of the differences in social status, values, and responsibilities between men and women, we can invite students to share their thoughts and opinions, and instructors would get a sense of how students perceive gender and its respective role.

Learning effectiveness can be enhanced through discussions among mixed-gender groups. Specifically, such discussions provide an opportunity for students to clarify their own values about gender norms. Through discussing with an open mind, where students can face each other as equals, students can learn to respect different views while reflecting on their own values.

Game Design

Students are required to answer questions to indicate their acceptance of different gender images. All questions are presented together with graphics. The whole game is composed of four sections. The first two games test students’ gender stereotypes and biases in “appearance” and “behavior” by their acceptance levels. Students are invited to ponder if appearance affects their attitude and perception of others, i.e., their preferences regarding making friends with people of particular features or style such as an untidy person, a fat or thin person, a girl with short hair; and if they accept them, to what extent they want to be associated with them such as becoming their spouse or good friends.

The Guttman scale [56] is used in measuring the attitude of each user in the first two games on appearance and behavior. Users are given an artwork which shows a certain appearance or behavior. They are asked whether they accept it from a list of 7 people who have varying levels of relationships. These 7 choices are arranged in a hierarchical order: the future spouse, a family member, a good friend, a friend, an acquaintance, an on-line-follower, and unacceptable. If a respondent can accept a certain appearance or behavior from his/her future spouse, it can be inferred that this respondent will accept all other people who have the same appearance or behavior. This reflects that the respondent has the highest acceptance level. At the end of each of these two games, a quantitative analysis on the acceptance level of the player will be presented. Instructors can encourage students to discuss two questions: Is people’s appearance or behavior a factor to consider before students form a certain

relationship with a person? What level of relationship will students be willing to have with someone who shows unconventional appearance or behavior, for example, a man who cooks or learns ballet?

In the last two games, students are invited to indicate whether an “occupation” or a “trait” is gender-neutral to test their gender stereotypes. In the game on occupation, students need to think if certain occupations are generally more suitable for females, males or both in the contemporary society. They might conform to social norms and traditional gender roles, and thus form an impression that particular occupations should be held by a particular gender but not both. For the game on trait, students are asked to determine if the features are suitable to describe a particular gender or both. This will test how they perceive the differences in personality traits between the two genders.

After they finish one of these two games, a qualitative analysis based on students’ choices will be provided in terms of gender stereotypes. For the game on occupation, instructors can make use of that opportunity to discuss with students that choices of career are influenced by many aspects such as income, social status, social expectations, and significant others, and that gender-specific traits are stereotypes. For the game on trait, students will have opportunities to review their degree of tolerance and acceptance of others as well as the level of respect for others and the tendency towards gender stereotyping. Instructors can encourage students to reflect on how they describe females, males or both genders, whether they have gender biases, and whether there are gender-specific traits.

The qualitative analysis presents the views and beliefs of students, which to a large extent are influenced by social requirements and views and expectations. To promote further discussion, instructors may suggest students to use the print-screen function to print out the analysis as the game does not record any data once the player exits the game. Suggestions can be given to encourage students to be more courageous and open-minded about the choice of career and views on gender-specific traits. Constructive suggestions might be given to encourage students to adopt a more open-minded approach to human diversity and equality. They are encouraged to reflect on the reasons why they believe certain occupations/traits are more suitable for a specific gender.

Tips for Instructors

Instructors may demonstrate the game in a class or an assembly and remind students to have an open mind when reading the feedback provided by the game. The feedback and guidance help students reflect on the issues of gender biases, look in-depth into these issues through discussions in or outside of the class, and try to summarize the different views. Instructors may encourage students to re-play the game so that they can observe any changes in their acceptance level of different gender images after discussion. As our impression and perception of women and men are largely influenced by our socialization through life experiences and interactions with others in our circle, instructors may encourage students to try to see how our society projects the images of gender and how it treats the two different genders. Moreover, our stereotypes and biases on ABOT are reinforced through our social interactions and expectations. We have to help those who might be confused, feel

uncomfortable or unable to accept. Instructors may encourage students to try to see gender disparity in a different way - the bottom line is to treat one another with respect and tolerance.

In terms of occupations, instructors can remind students to be respectful and tolerant of others in terms of career choices based on one's interests, abilities, and adaptive development. Students can explore the possibilities of certain occupations, which traditionally are dominated by one gender, from a different angle. Will they accept themselves to take up the work which is normally performed by the opposite gender such as a male nurse and a female electrician?

Instructors can bring in their personal experiences and other real-life examples to broaden student's thinking on the issue. Discussions between female and male students should be encouraged to help students understand what the other gender think or experience in their daily life. In cases such as single-gender schools, instructors can encourage students to use the teaching material after class and discuss with their family members. Social workers or counselors can use the teaching material for individual or group counseling.

POSITIVE YOUTH DEVELOPMENT CONSTRUCTS

The game was specially designed to contribute to one of the 15 positive youth development (PYD) constructs, i.e., "Clear and positive identity." They have been identified as effective components of PYD programs [57]. Incorporating all the 15 constructs, the project P.A.T.H.S. is an evidence-based and multi-years universal PYD program [58, 59]. The objectives of the project are to promote a holistic development of adolescents in Hong Kong by providing opportunities and recognition to develop competence and skills which are conducive to PYD. The program aims at promoting bonding and resilience among adolescents, enhancing core competencies, training critical thinking skills, and cultivating healthy beliefs and values. The project provides a primary prevention program through 20 hours in Secondary 1 to 3 (Grades 7-9). A total of 120 teaching units (each 30 minutes) covering 15 PYD constructs. It also provides a tier-two program to meet the needs of students with greater psycho-social needs. Evaluation studies showed that the project was efficacious in addressing psychosocial risk factors during adolescence [58]. In an effort to revamp the content by adding a DPYD game, a new curriculum unit was designed. It can be used independently or to support two existing teaching units. A brief description of these two related units is provided below.

Related Teaching Units: Concept Maps, Learning Targets, and Teaching Tips

The two related teaching units are named SX2.2 "Men...Women...Not" and SX2.3 "You Can' be Good at this." They were designed to promote sex education for S2 (Grade 8). For SX2.2, the learning targets are to understand gender stereotypes and understand students' views and values on the gender roles. It focuses on the construct of "Prosocial Norms" and "Social Competence." The concept map is presented in Figure 2.

Figure 2. Concept map for teaching unit SX2.2.

Teaching Points for the Teaching Unit SX2.2

There are a set of expectations towards the two genders in our daily life, schooling, choice of career and family. It is often affected by gender stereotypes and has a direct impact on an individual from different people such as parents at home and teachers from schools. Those gender stereotypes on the two genders also have an impact on people's behaviors, characters, and values. Instructors should understand those gender stereotypes and share with students what they are and how they affect our perceptions of gender consciously and unconsciously.

In the teaching unit, students could reflect on one's own personal views toward gender roles, and be encouraged to treat the opposite sex with a fair and open attitude. Instructors can guide students to reflect on the reasons for having different expectations on people of different gender and remind students to respect others even when our behaviors, character, and values are different.

For SX2.3, the learning targets are to understand how stereotyping affects career decisions and help students to learn about the importance of gender equality. It focuses on the construct of "Self-determination" and "Moral Competence."

Figure 3. Concept map for teaching unit SX2.3.

Teaching Points for the Teaching Unit SX2.3

Gender stereotypes affect everyone in the public domain as our society often sets inflexible impression towards both male and female. Those impressions and ideas directly affect our choices for careers and people might see certain careers exclusively for male or female without questioning the rationale behind. In the theory of planned behavior, it links one's beliefs and behaviors. Our attitude toward others' behaviors, the subjective norms, and perceived behavioral control, all combined to shape our behavioral intentions and behaviors [60]. Instructors should discuss those impressions and ideas with students and listen and understand where students are coming from when they share their thoughts on the topic.

Instructors may make the best use of this unit to promote gender equality and suggest ways for students to practice gender equality in daily life. Encourage students to think thoroughly if their personal ideal occupation is restricted by gender stereotypes through class discussion. Besides, it is a good opportunity to help students reflect on whether they or others in the community have engaged in sexual discrimination behavior. If so, discuss some of the ways students can do to minimize that from happening again. We can increase students' empathy towards the victims of sexual discrimination by inviting them to consider victims' feelings so that they realize that they should treat both genders in a fair way.

Instructors can make use of the reference materials provided to supplement their teaching of this unit when using the game with students. The materials can be found in unit ID3.2 "The male-female dichotomy?" There are reflection questions available for instructors to use with students at the end of the teaching section.

In the game, students were given the opportunity to think about how our attitude and perception toward someone are affected by his/her appearance which affects their relationship with others. They can reflect on their preference regarding making friends with a person with particular features or style i.e., a fat person, an untidy person, a very thin person or a girl with short hair, etc. Students can be invited to actively engage in self-reflection on their own personal values towards gender roles and how that affects their behaviors. Also, students are invited to think if certain occupations are generally more suitable for females, males or both currently in society.

To sum up, the games support the teaching units to help promote and practice gender equality, increase awareness of gender stereotypes, and cultivate empathy for victims of sexual discrimination among students.

USERS' FEEDBACK

To collect feedback from users, convenient samples of adolescents and young adults were invited to use the game. Participants were invited to reflect on their experiences and comment on the game design.

The following comments came from a 15-year old Chinese female student studying in an international school in Shanghai. Parental and participant's consents were obtained to use the game and her comments on her experience.

Appearance

"For me personally, this exercise was not extremely eye-opening because I think that in my upbringing in an international school, I've been exposed to a range of students and friends from many different countries and with different physical appearances. Thus, my responses for most of the categories remained unchanged throughout the game."

Behavior

"For the behavior game, I was entirely sure what the main learning aim was when playing. Based on my understanding, the game was set up in such a way that typical assumptions about girls and boys were provided, and I would pick what type of relationship I would be willing to be in. However, I think that one aspect that this game overlooks is the player's personal values. For the traits that are stereotyped as non-feminine, such as "behaving violently with others" and "fights with others physically," by clicking not acceptable does not necessarily mean that the player is against females specifically doing this, it may be that the behavior overall is something that people should not have. To account for players' personal values, it may be useful to ask players to pick whether or not they would accept a relationship with a certain behavior for females and males separately. For example, "What relationships can you accept to form with a young lady who does not know how to

cook?” and “What relationships can you accept to form with a young man who does not know how to cook?” could both be asked in the game.”

Occupation

“I found this game interesting because there were a lot of occupation options offered. It helped reinforced ideas supporting career gender equality, such as how males can also be home-carers, and females can be engineers or programmers. However, I felt like the game was a bit repetitive.

Towards the end of the game, it was easy to fall into the trap of just putting all the occupation blocks into the “both” category without thinking or reflecting on what my opinion really was.”

Traits

“Throughout the first run-through this game, I found that there were definitely some biases I held towards what traits are considered feminine or masculine. After playing the game, I think that I was more self-aware of these biases. Similar to the occupation game, I think that due to the repetitive nature of just placing traits into different categories, it was less effective in self-reflection towards the end of the game.”

A 19-year old college student from the United States wrote on one of the games ‘Behavior’:

“I do not think there is much that needs improvement here. It is fine as it is. I believe this section was well done. It conveys the message of breaking down stereotypes and being more accepting clearly to the player.”

DISCUSSION

Different times impose different demands and expectations on either gender, which play a crucial role in maintaining social stability and harmony. As we grow up, the external world including families, schools, communities, and societies instill into us identities of what men and women should be and what is expected of each gender. This teaching unit helps students examine in depth the positive and negative implications of these notions with regard to gender equality. The instructors can lead students to think of examples of heroes/heroines of all times from around the world and talk about their achievements. As a basic principle for human relationships in any modern society, individuality should be respected. Women and men develop their own distinct qualities such as physical appearance, physique and thought pattern through socialization since birth. On one hand, we should treat one another with respect, acceptance, and tolerance, and on the other, we must help keep this principle through primary prevention to provide early education, clarification of values, and treatment if necessary when it comes to the issues of gender inequality. Our society should strive to recognize and rectify inequality should gender prejudice and discrimination happen. Students should be reminded

that people should not be limited by gender, and they are free to follow their passion and fulfill their dreams regardless of society's perception of gender roles.

From the users' feedbacks, it was suggested that the games successfully evoked adolescents to rethink about gender roles and their perception of gender. Particularly, the two users found the occupation and trait modules inspiring and interesting. They reported that the game in the occupation module helped to reinforce gender equality in occupation choice, especially in this modern society, man could be a home carer, whereas women could work in the science and engineering industry. It seems that this game can help students understand the constraint by gender stereotypes and gender norms [61] and expand their options in their future career choices [62]. For the trait module, it was reported to have a similar effect with the occupational module. Users reported to be more self-aware of their gender-biased traits, which they have formed unconsciously in the past. However, whether they will adopt a higher level of acceptance remains unknown. This calls for further research.

The feedback on the appearance and behavioral modules were not as positive as the occupation and trait modules. Users expressed that the appearance game did not offer a surprising experience because they were used to the diversity in people. One further explained that she had many opportunities in life encountering people from different countries with different physical appearances properly because she studied in an international school. Further studies are recommended to include players of different backgrounds. The behavioral module was reported to be confusing that the user had difficulties understanding the learning purpose of the game. One user pointed out that the cause of his confusion could be design-related as it disregarded the personal value of the participants. This issue deserves further examination.

The initial findings from users' feedback were partially consistent with previous research that education on gender stereotype helps the young ones to be less gender-biased [51]. Participants suggested 2 out of the 4 modules of the game could be further improved in order to clearly deliver the game content to address gender stereotype. The qualitative comments were also supported by the study of Bigler and Liben [52] that classification trainings such as occupational sorting were crucial for counter-stereotypic information, potentially reducing gender stereotype in young people. In addition, utilizing computer games in the education context suggested by Squire [53] is supported in the current study. Junior secondary school students generally enjoyed learning through playing computer games, echoing the study by Weber and Custer [55] that early adolescents benefit from DGBL. This study provided a background for testing the effectiveness of the game.

To sum up, the use of GBL materials do have benefits over traditional teaching and learning format such as learning from textbooks. In this game, designers have considered the principles of attractiveness of the pictures and characters, the background of the screens, the engagement and responses of the participants in the activities and the feature of repeated use when putting the games together. With the help and guidance of the instructors and peer interactions, students were motivated to participate in the activities and learn in a fun and educational atmosphere on gender equity and stereotypes at the pace of the class and at home as well.

LIMITATIONS

A problem with the current study was the generalizability of its results. Compared to quantitative research studies, the findings of a qualitative study cannot be extended to the greater population as the data from a qualitative study are not examined to ascertain whether the findings are statistically significant or due to chance [63]. The qualitative data should be interpreted with caution.

Testing the Effectiveness

This study did not obtain any quantitative data on the level of gender stereotype of the middle school students. In the future, a thorough quantitative research can be conducted to test the effectiveness of the game in minimizing gender stereotype among adolescents. Many well-established scales have been developed to measure the level of stereotype including the Gender Role Attitude Scale (GRAS), the Bem Sex Role Inventory (BSRI), the Personal Endorsement of Gender Stereotypes Scale, and IAT (implicit association test). These measurements have been validated in Asian countries including Japan [64], Taiwan [65], and China [66]. Adopting these measurements to examine gender stereotype would be suitable for future research. To test the effectiveness of the game, a pre-test and post-test design is recommended. Basically, the study could first examine the level of gender stereotype in secondary school students using the above measurements before introducing the electronic game. After students have completed their learning, the same set of questionnaires could be done by the same group of students in order to find out if there are changes in their level of gender stereotype by comparing the scores before and after introducing the materials. From that, the effectiveness of the materials could be concluded in our target group. It is also worth investigating whether the games could be utilized for children aged between 8 to 11 using the suggested design above as evidence has proven that children as young as aged 8 can develop gender stereotype in academic and occupation preference [67]. Apart from examining the gender stereotype, other factors that are affected by gender stereotype such as self-esteem, body shapes, and subjective wellbeing could be explored in addition to the effectiveness of the games.

After testing the effectiveness of the study, future studies can focus on the impact of teacher involvement in maximizing the effect of the game. The role of teachers in educational activities that minimize gender stereotype has been confirmed in a study [51]. Even though we have assumed the involvement of teachers in delivering the materials, future exploratory study could be conducted to examine the teaching and learning processes of our DPYD games. A cross-sectional study comparing the level of gender stereotype between the group of students with teachers as guidance and the group of students without teacher involvement would be ideal. This could further inform the teaching and learning processes to maximize the effect.

CONCLUSION

The key finding is that the game seems to be beneficial for secondary school students in terms of enhancing their awareness and reducing the effect of gender stereotypes and biases. A few issues are raised in this study that required further research on the issue. Some adjustments are needed on the use of the game for different levels of prevention. The results suggested a need to conduct exploratory and quantitative studies to gain a better understanding of the effectiveness of the materials and its utilization among students.

ACKNOWLEDGMENTS

The design and production of the 7 digital games introduced in this special issue, the preparation of this work, and the Project P.A.T.H.S. were financially supported by The Hong Kong Jockey Club Charities Trust. Readers may request free copies for non-commercial purposes of these games by contacting Dr. TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This chapter is based with permission on a paper adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

ABSTRACT

This chapter presents a brief literature review on cognitive biases among early adolescents who grow up in the digital age. It then describes the design and production of a digital positive youth development (DPYD) game to strengthen cognitive competence. A description of how to make the best use of the game together with the use of related teaching units of the project P.A.T.H.S. for primary prevention is given. To demonstrate the potential impact, users' feedback of an adult male college student from the United States and a female early adolescent from China are presented. A discussion of how to use the game for promoting positive youth development is presented.

INTRODUCTION

Living in a digital age implies processing large amounts of information daily for almost every young person. To verify the truthfulness of information requires much time, effort, and know-how. To check the accuracy of every piece of information received is literally impossible. Children and adolescents may not be adequately prepared for an environment in

* Corresponding Author's Email: sarahlee@hkbu.edu.hk.

which information overwhelms. A famous technology and social media scholar, danah boyd [1] raised an important issue that many people asked students not to trust Wikipedia, but failed to teach them critical research skills to discover the trustworthiness of any one piece of information. She argued that distrust of media and selective research to reaffirm one's own selective exposure, interpretation, and retention of information cannot help strengthen media literacy of anyone, including young people [1]. However, young people are heavy users of social media, which might contain dis-ordered information including hate speech, slander, rumors, and offending, discrediting, badmouthing and misleading narratives. Using deep-fakes is also commonly found [2-4].

In this day and age, the media landscape is developing rapidly. An individual's web search experience is tailored specifically to his/her interests or needs. Due to independent journalism and press freedom, the amount of news people produce on the internet every day is mind-boggling. At the same time, the phenomena of fake news, biased news, and content farms are rife in society.

Recently, many places in the world, including Hong Kong, have been deluged with rumors, where inconceivable rumors spread on social networking sites and apps rapidly. These rumors might come from an edited video, a misleading report, or simply fake news. Rumors without any evidence are dangerous as they would amplify collective fear, confusion, and conflict in society.

On an individual level, people are likely to choose or read the information that supports their stands or worldview. Furthermore, different social networking sites like Facebook or Twitter are able to filter information it presents to its users which corresponds to their political beliefs, leading to the formation of echo chambers [5]. Many people stare at their smartphone all day for updating the latest news and it may lead to various health problems. It is found that using social media during the weekday is correlated with lower sleeping quality [6]. Moreover, social media addiction is negatively correlated with adolescents' academic performance [7]. For the psychological aspect, it is reported that social media addiction is associated with mental health disorders [7, 8]. People may suffer from stress, anxiety, and depression when they spend a long time reading similar kinds of depressing news through social media.

Since people tend to read and share information that is one-sided due to echo chamber effects, it may lead to the distortion of the truth or moral choices [9]. It has even caused more negative consequences. For instance, social media addiction was significantly correlated with hyperactivity, conduct problems and sedentary behavior [10].

As a result, it is crucial to understand the viewpoints from different stakeholders. Due to the ubiquity of fake news nowadays, adolescents should be trained to make a rational judgement and counter fake news or rumors. It can be done by equipping them with independent thinking skills and social conscience.

LITERATURE REVIEW

Since Nielsen [11] coined the term "information pollution" in 2003, the information ecosystems in different countries have gone through drastic changes according to intertwined factors which include history, culture, politics, economy, education, adoption of information

and communication technology (ICT), media law, and press systems [12]. Global concerns have increased over the precarious nature, polarized content, the instantaneous process, and harmful impact of “information disorder” which include mis-, dis-, and mal-information. The intention, truthfulness, and whether harmful or not are the criteria to differentiate these three types of “disorder” [13]. Information disorder and manipulation have become global issues of prime concern as these phenomena are found in almost every aspect of life for everyone. Table 1 shows the differences.

Table 1. Compare and Contrast Mis-, Dis-, and Mal-information

	Intention to harm	Truthfulness	Harmfulness	Example
Mis-information	N	N	Depends	To spread, without knowing it is false, information in attempt to offer help, e.g., rumors, insults, and pranks.
Dis-information	Y	N	Y	To produce and spread false information with political, financial, psychological, or social intentions, e.g., captioned photos or GIFs, manipulated or fabricated images.
Mal-information	Y	Y	Y	To harm a person or his/her reputation by sharing genuine information, e.g., doxing and trolling (deliberately posting inflammatory or offensive content).

Mis-information is false information disseminated without harmful intent. Dis-information is false information created and shared by people with harmful intent. Mal-information is the sharing of “genuine” information with the intent to harm a person or group. Wardle [13] classified seven types of mis- and dis-information which include 1) satire or parody; 2) false connection; 3) misleading content; 4) false context; 5) imposter content; 6) manipulated content and 7) fabricated content. Adolescents need to enhance media literacy skills to handle information disorder and manipulation.

Negative Impacts

For early adolescents, knowing how to ascertain the credibility of any one piece of information received may be necessary but certainly not sufficient for getting rid of troubles in the digital world [14]. Examples include harming others, being cheated, making wrong decisions, wasting time and money, etc., through spreading hate speech, making statements that are misleading or untrue, or claims based on unverified messages being circulated online, and further spreading of debunked rumor.

For young adults who have the right to vote, the negative impact may be a challenge to democracies [15]. In the political aspect, the coordinated campaign could be an orchestrated activity which aims at spreading incorrect content on different social media. The result could possibly undermine the legitimacy of an election, negatively influencing the prestige of a foreign company, or construct a hateful relationship that drives a military operation [15]. Exposure to biased media contents, the inability to discern the credibility of information, the

influence of reference groups, and even the algorithm used by search engines are factors related to the failure of making correct decisions.

According to MIT news [16], an analysis of posts on Twitter by three million people between 2006 and 2017 shows that false information spread six times faster than facts since it takes time to determine the correctness of a piece of news, while the false information could have already been widely spread. The research project also finds that it was people, not robots, who spread misleading information.

Cognitive Biases

Cognitive biases refer to the systematic thinking errors that influence the decision-making of a person when he/she is handling information [17]. It is observed that a higher level of approach bias was correlated with higher alcohol use among male adolescents [18]. The correlation was also found between attentional bias and alcohol use among adolescents [18]. Moreover, previous research found that cognitive biases including interpretation, self-referential memory and facial expression recognition are significantly associated with an adolescent's well-being, depression and anxiety symptoms [19, 20]. Besides, it is reported that cognitive biases play a mediating role between shyness and society anxiety among early adolescents [21]. These show that cognitive biases affect adolescents in different aspects of their lives.

Cognitive traps are everywhere. Biased and false information which include clickbait, fabricated journalism, and sponsored content are commonly found in digital communication. With rapid advancement in information and communication technology (ICT), the cost of spreading such false information and biased views has been largely reduced. Social media offers an opportunity that allows information to be spread widely and instantly which may influence decision making [22]. Fake news is defined as make-up information aimed to deceive readers [23], and has shaped many economic-political-cultural issues which include hate speech, biased views, and misinformed citizens. From the psycho-social-moral perspectives, the sensational and provocative fake news provokes readers emotionally and appeals to irrationality, and as a result misinforms the public [24]. The spreading of false claims potentially facilitates identity and emotional debates and struggles among people, resulting in a polarized society, and "losers" in the situation lose their confidence in society due to the misinformation [24]. This is partly because individuals tend to support pre-conceived stances or preferred explanations even though information might be conflicting [25]. Selective exposure theories [26] and cognitive dissonance theory [27] are useful in explaining such a phenomenon.

It is undeniable that social media and smartphone have brought huge influence among adolescents. One reason is that a large number of adolescents and their parents spend more than two hours on their smartphones daily. The uses and gratification approach is still adopted to understand why and how people use social media. Nevertheless, Tversky and Kahneman [28] challenged the assumption of individual characteristics and decisions under the uses and gratification approach. Besides, Brofenbrenner [29] emphasized a person's relationships within communities and the wider society instead of individual relationships. In order to handle the challenges, the adolescents' identity, characteristics, personal habits, and

environment are proved to have different kinds of influence on adolescents in the Media Practice Model by Steele and Brown [30]. The model is an initial integration of Bandura's social learning theory and Gerbner's cultivation theory, which are two significant theories about media influence. More attention is still required to enhance the measurement of media use. Besides, more longitudinal research can be done to understand the influences of new media so as to find whether and how the large number of essential variables can lead to the cumulative effects.

Rumor

Another frequently occurring information error in society nowadays is rumors. Based on the rumor theory, rumor is a collective behavior in which people offer, interpret and evaluate information in an event or situation under ambiguity and relative collective ignorance [31]. Anxiety and uncertainty occur in ambiguous situations, especially when horrible events happen [32]. Extreme situations such as natural disasters stimulate people's anxiety and stress, and from that they start making up rumors and false information, creating more anxiety in the public [31]. It was found that social media such as Twitter are used to spread information about crises and the reliability of the information is questionable [33]. Rumors also frequently occur in organisations and institutions. A study which investigated rumors within a hospital undergoing changes found that employees who heard of negative rumors reported higher level of stress compared to those who heard of positive rumors [34].

At an individual level, indirect bullying among young adolescent boys and girls such as spreading rumors predicts anxiety, depression and withdrawal behaviors [35]. Besides rumors, gossip can also be categorically sensitive and very difficult if not impossible to ignore, and teens are particularly susceptible to it. These spread quickly on social media, and as frequent users, the social lives of young people can be heavily affected. Gossip and rumors targeting individuals can result in damaging teenagers' self-confidence, and as a result affect their self-esteem with possible negative consequences such as depression, suicidal thoughts, eating disorders, anxiety, and many other issues [36]. Reliable information from creditable resources is the key to suppress groundless rumors and false information, resulting in a decrease in anxiety [31]. This process requires decision making, which can be rational, irrational or non-rational [37]. However, the process of obtaining reliable information is not simple, as it requires multiple efforts from an individual.

Cognitive Illusions

Cognitive illusions are often the barrier that prevents people from making a rational judgment on information they receive. These so-called cognitive "errors" include overconfidence bias, which means people having strong belief that the information or answer they have chosen is correct; conjunction fallacy, defined as the misconception to assume a specific condition being more possible than a general one, and base-rated fallacy, which describes when people ignore the original data and rely heavily on the current information

[38]. From that, we can conclude that our judgement is not always rational, and people fall into cognitive traps.

Through recognising and understanding the cognitive illusions, people can avoid cognitive errors and deceptions with their own judgement [38]. Judgement or decision making is a type of cognitive process, which can be carried out in a critical or uncritical manner [39]. Critical thinking, which is the ability to think logically, is proven to be effective in preventing biases [40].

Critical Thinking

Critical thinking is crucial in people's lives due to a few reasons. According to Vieira, Tenreiro-Vieira and Martins [41], critical thinking should be taught to students, as individuals are wrongly assumed to be able to think critically and make rational decisions, avoid egocentric attitude, and living, working and functioning efficiently in this modern complex society. People constantly have to assess and obtain different information. In fact, educators are promoting critical thinking as it is related to personal disposition, academic performance and leadership [42]. Cognitive competence including critical thinking and creative thinking also contributes to adolescent's positive development, especially in learning and wellbeing [43].

Therefore, training adolescent critical thinking is beneficial to their development. Utilising the problem-based learning approach, which simulates ill-structured and complicated situations in an online environment, is found to be effective in enhancing critical thinking skills in young people [44]. In addition, critical thinking also includes the ability to justify statements and ideas with adequate information and examples in early adolescents [45]. Carmichael and Farrell [46] reported that with the use of modern technology, an online critical thinking blackboard site is created for the young ones to practice critical thinking. However, its effectiveness depends on the students' level of development, their knowledge in technology, and their levels of engagement. In fact, students with better computing skills score higher in critical thinking tasks, indicating a technology-rich environment is associated with the development of critical thinking ability [47]. Information literacy also promotes critical thinking skills in young people which can be developed via skills training [48].

To avoid falling prey to cognitive traps and false information, the development of critical thinking is crucial and beneficial to young people's development. Digital game-based learning has been proven to be effective for junior secondary school students [49]. Digital games, especially "dialogue games" that adopt the features of "building blocks game" with instructional goals alone support the development of critical thinking and reasoning skills [50]. The learning materials are designed based on these previous findings, incorporating digital games and training for critical thinking skills. The materials simulate cognitive traps that people encounter in daily life in a game format in order to allow students to learn and train in a fun and interactive way.

To summarize, while part of the solution may rest on enabling adolescents to enhance their media literacy skills, it has to be noted that young people might believe in something not because of the information itself, but because it came from their peers. Against this

background, a DPYD game which adopts the game-based learning approach could be an efficient and effective teaching and learning strategy.

GAME DESIGN

The theme of this digital game is “Think critically, discern wisely” and the name is “The great thinking adventure -- 51 cognitive traps.” In our daily life, thinking is a basic function of the mind. For children and early adolescents who have yet to develop their cognitive competence, it is easy for them to fall into cognitive traps. The consequence may be undesirable if not harmful – it may lead them to adverse results such as using false information or making decisions based on wrong judgements. In order to be able to identify and avoid fallacies, they have to learn critical thinking skills which are of paramount importance in the process of positive youth development (PYD). Educators need to try to incorporate the cultivation and practice of critical thinking in the curriculum as much as possible so that students get the opportunity to develop their skills in thinking critically in their daily life. The education systems in some parts of the world put more priority on the academic achievements than other areas. In places where the tradition of rote learning is emphasized, students might be less likely to practice critical thinking skills in and outside of classrooms. This game is an effective tool to engage students in pondering on thinking principles and recognizing the traps that anyone may fall into if he/she does not pay close attention to the thinking processes. The cognitive traps categories and definitions are referenced mainly from the book by Dobelli [51]. The majority of the contents in the game (over 90%) is original.

It challenges students to question their assumptions and cognition of cause-effect relationships, rational and logical thinking, prejudice, and biases, and learn to become an independent, logical, and rational thinker. The game introduces 51 cognitive traps and asks questions related to common phenomena. It analyses students’ mistakes based on calculated scores, and it provides feedback on difficulties that arise during the game.

Objectives

The game is designed for Grade 9 students to help them recognize the 51 types of cognitive traps, to learn about the primary thinking principles and to distinguish the authenticity of information encountered in everyday life. On the cognitive aspect, the game aims to help students understand the 51 cognitive traps and the principles of rational thinking, enhance the capacity for identifying the cognitive traps, and understand the use of thinking ability effectively. On the emotional aspect, students can reduce emotional distress in daily life caused by making mistakes due to not being able to think critically. Additionally, on the behavioral aspect, it is hoped that students can not only utilize the thinking ability to assist themselves to achieve better outcomes, but also be able to help others recognize their irrational thinking and beliefs, and thus develop a chain effect in the process.

Teaching and Learning Methods

The teaching material in the game provides feedback and guidance according to students' different responses to the cognitive trap test. It also provides learning contents at three levels. First, it provides performance tests on thinking principles. The results are shown as numeric scores which reflect the degree of mastery of the five major thinking principles. Students can always replay the game if they wish to obtain a higher score. Second, there are four challenge areas. Each area is composed of three levels, from easy to difficult. After the completion of each area, accumulated scores in each of the five thinking principles are displayed in a pentagram. Finally, detailed feedback for each principle will be provided upon clicking the appropriate places in the pentagram.

Storyline

At the beginning of the game, the player is shopping in the supermarket and he/she notices a sale at half price of a certain brand of orange juice. He/she then buys the item thinking it is a good deal. Upon returning home, his/her mother points out that it is in fact not a good deal because the usual price is lower than the price it was offered at the sale price. At that moment, the player becomes very upset and he/she decides to study the secret book of 51 cognitive traps to gain more knowledge about thinking skills in order to avoid being captured by the **"SPIDER,"** which is the acronym for **S**elf-recognition Bias, **P**robability and Statistic Error, **L**ack of **I**ndependent Thinking, **E**motional Bias and **R**esult-Oriented Bias. By answering questions in the game, students will deepen their understanding of cognitive fallacies and strengthen their ability to avoid such fallacies.

Breakdown and Procedures

The game is divided into four challenge areas, and each of the first three areas shows 17 types of cognitive traps and randomly presents 15 test items. In the final area, items covering all the 51 traps will be randomly shown, increasing the difficulty level of the game. Each area has three different sections with varying levels of difficulty. In the first level, students are asked to choose between two options, and two wrong attempts are allowed. In the second level, three options are given, allowing three wrong attempts. In the third section, students have to choose the right one from four options, and they are also allowed four wrong attempts to continue the game.

Instructors can play the storyline of the game (10 minutes) with the class to introduce the game. Students can play the game in groups. It will take about 15 to 30 minutes to complete each challenge area depending on how much time students need to review the definitions and examples. To maximize the learning outcomes, it is recommended that instructors encourage students to aim at achieving error-free answers but not shortening the time for completing the game. Instructors can also allocate some time for class discussion subsequent to game completion. Students should be encouraged to continue playing the game repeatedly and at home individually because test items are randomly drawn from a pool of 459 items. The

completion of the four challenge areas will total to only 150 items, about one-third from the pool. Thus, students will have the opportunity to tackle different questions when they replay the game.

TIPS FOR INSTRUCTORS AND TEACHING HIGHLIGHTS

There are plenty of ways to classify cognitive traps, and “SPIDER” represents one of the many ways. The purpose of this classification is to facilitate students’ identification of different cognitive traps. However, instructors have to be mindful that we must be open in grouping cognitive traps as a single trap which can be classified into different categories to avoid unnecessary debates.

To facilitate students’ memorization and understanding of the cognitive traps, they are named by corresponding Chinese idioms. However, the definitions of the traps may be slightly different from the original meanings of the idioms. Therefore, instructors should encourage students to read each definition of the trap carefully before starting the game. Students are also able to review such definitions during the game if needed. Students may encounter some neutral descriptions in the tests. For example, “The Nazis triggered the Second World War.” This sentence implies the “simplification” cognitive trap, i.e., accepting an easily understood phenomenon as historical truth. Hence, the focus of the test is NOT on differentiating between right and wrong, but on learning to identify the possibility of falling into different cognitive traps. As a result, students can think independently and make decisions carefully.

In the feedback section, “Do not avoid thinking”, “Understanding thinking principles,” “Beware of bias,” “Comply with logic” and “Open mind, open heart” are the five basic thinking principles. In fact, there is the sixth principle “Putting oneself in the place of another person” which is not frequently found in this game. Mastering these principles helps students identify and avoid cognitive traps. Instructors should encourage students to read the feedback generated carefully according to their responses to the test items so that they can know their capabilities and pay attention to the areas for improvement.

Even if students get high scores on the tests, they should still be reminded not to become complacent over the test performance. Instead, they should use their cognitive ability modestly to help others. Instructors should remind students that there is no need to compare their own results with others. The scores are for reference only and they are just indicators reflecting their performance in this game. Therefore, students should not be upset when they get low scores. Instructors may encourage them to play the game repeatedly and read carefully the definitions and examples of each cognitive trap to deepen their understanding.

SUGGESTIONS ON USAGE FOR INSTRUCTORS

Instructors can arouse students’ interest in using the material and enhance their motivation of improving their cognitive ability through demonstration in classes or an assembly. Instructors can explain the teaching and learning method in classes and ask

students to use the teaching materials on their own after class. They should also encourage students to refer to the feedback, set goals, and then replay the game.

When students get to the hardest level of the game, where there are four options available to choose from, they might lack motivation to think clearly. Discussion in class can make the game more interesting as students can talk about which option they will pick and the reasons behind. Instructors can facilitate a lively discussion and challenge students' thinking processes accordingly. Nonetheless, it can be frustrating if students cannot pass the level once or for a few times. They might find the games tedious and time-consuming, and thus lose interest in playing at a more difficult level. Strategies like working in pairs and groups can help motivate students to understand the teaching materials and work on the game together. Real-life examples can be used to stimulate students' interest, for example, finishing up the whole pack of snack that tastes bad because one has paid for it already, or keep pressing the button of the lift thinking it will come sooner. Encouraging students to look at the tips for the question and to check if they understand the trap accurately will help.

Finally, instructors and social workers may use the material for competitions or group games. It is recommended to complete the first level of the first three challenge areas initially. Students can try the first round as it is easier because there are only two choices. To maintain students' interest, test questions will be presented randomly in the game. Test items shown in the most difficult area, the fourth challenge area, are randomly drawn from all the 51 traps. Lively discussion can stimulate students' critical thinking skills and allow instructors to understand their thinking processes, making it easier to find strategies to help them improve their capacities to think critically.

CONSTRUCT: COGNITIVE COMPETENCE

Besides the electronic game, there are some supplementary teaching materials such as worksheets and reflection questions available for instructors to use when introducing this game to the class. For example, instructors can make use of the worksheet "The five major cognitive traps categories" once the "SPIDER" is introduced. Instructors can explain what SPIDER stands for and how they associate with cognitive traps so that students can remember the various categories more easily. In the worksheet, instructors may identify some common scenarios experienced in everyday life situations, and remind students to be aware of inadvertently falling into those traps. One or two examples from each category can be used to open up the discussion in class before playing the game.

An example of each category will be given here for instructors' reference (taken from Appendix 3 of the teaching unit CC3.1). In the "Self-recognition bias" category, it is common to think that "I won the game because my skills were better, but I lost the game because I did not have enough sleep the previous night."

In the probability and statistic error category, a statement goes: "Since the successive terrorist attacks in Europe in recent years, the number of people of Hong Kong visiting Europe has decreased." However, our interpretation of it as "The people of Hong Kong are worried that terrorist attacks might take place and therefore they do not want to go to Europe" might not be accurate because people neglect the fact that the chance of terrorist attacks is much lower when compared to traffic accidents.

In the category of “Lack of independent thinking”, it is often assumed that experts know best that “the theory of scientist must be correct.” In fact, being a scientist with professional knowledge does not mean that their theory must be correct. Instructors can make use of more examples to illustrate the point especially in the field of the medical profession. People might trust and follow the advice of doctors and other medical professionals without doubt simply because they are the experts of the field.

In the emotional bias category, students are challenged to think rationally rather than emotionally. For example, “Someone asked me to donate after she gave me a small gift. I agreed to donate because I did not feel good to refuse.” This happens in real life where we would do something reluctantly because we would feel bad to refuse so, or the person has helped us before. Others give us a small gift, and we feel like we owe them a favor. Nonetheless, it does not mean that we must agree to the request of others. We should consider if that is something we truly want to do and the right thing to do rather than simply agree to return a favor.

For the “result-oriented bias” category, instructors can share an example of “Plenty of people smoke and live a long life. Therefore, smoking should not have much impact on my health and my life expectancy.” Although cases of smoking and longevity may look appealing, we should not ignore the dangers of smoking or overestimate chances of living a long life with smoking. It is easy for us to spot and emphasize the positive outcome when justifying certain behaviors. For example, students sometimes overemphasize individuals who do not study hard but get promoted or admitted to universities. Instructors could remind them to look into the facts and see the full picture rather than a small portion of the odds.

It is very easy for us to fall into cognitive traps in our daily lives, which could lead to self-induced deception and ignorance, self-blame, missed opportunities or misjudgment and the like. Instructors can lead a reflection session with students and encourage them to list out some examples that show how someone falls into any cognitive traps from their experiences, and invite the class to discuss those examples and try to analyse which category the example falls into. A reflection worksheet accompanies the unit.

THE SIX PRIMARY THINKING PRINCIPLES

There is another supplementary worksheet on this theme. Instructors can introduce students to the six primary thinking principles summarized by Tsui [52], which can assist them to think critically and discern wisely. They are as follows:

1. Do not avoid thinking: think independently, do not appeal to authority, and do not blindly follow conventional beliefs
2. Understand thinking principle I: be rational, be objective, and be less emotional
3. Understand thinking principle II: treat others as you want to be treated
4. Beware of bias: be aware of all kinds of prejudice and bias
5. Comply with logic: be logical in reasoning, do not generalize, and base judgment on facts
6. Keep an open mind, open heart: learn to question, keep an open mind and respect others’ beliefs

Instructors can make use of the principles creatively and discuss with students how they can memorize them and put them to good use in their lives. Students can be encouraged to call out others' thinking fallacies in a constructive and respectful manner, for example, to help one another practice thinking more critically day by day.

Learning to think critically and independently is very important especially for our young people, who face an overwhelming amount of data and information on a daily basis. Being able to understand and recognize one's own thinking when falling into a cognitive trap will be a great asset for everyone. We are all susceptible to thinking fallacies and we have to learn to accept the fact, have the integrity to admit mistakes and be open-minded to others' perspectives. On the other hand, knowing all the cognitive traps does not give us a right to be arrogant or dominate others with our own thinking. It is hoped that students can learn these important skills in the teaching unit and be kind and logical when attempting to point out others' thinking fallacies to avoid denigration.

REFLECTION AND FEEDBACK

After playing the game, a Chinese girl aged 15 studying in an international school in Shanghai wrote the following reflection. Parental consent to play the game and publish her views was obtained.

"I really enjoyed reading about the different types of biases because I think that they are very applicable to life, whether it's through conducting scientific research or having small talk with someone. I also liked playing this game because previously, I had not been taught much about biases. So it was very eye-opening to me when I realized that my line of reasoning or logic would be considered biased. For example, I have definitely fallen into the trap of buying over-priced items because they were on 'sale' and marked down (the contrast effect). The game itself was fun to play around with. The rules were easy to understand, and the animation was entertaining. Overall, I think that this game has given me the knowledge and tools to think in a more objective way regarding stories and scenarios."

The following is written by a male young adult aged 19 studying at a university in the United States:

"I really enjoyed this game since I definitely learned a lot about the biases that I have from my day to day life and how to use my knowledge of them to make better decisions. The quizzes definitely solidified my understanding of the biases. I have actually learned a lot from this game and believe I can reduce a lot of my logical fallacies in my day to day life from now on."

DISCUSSION

In this digital age, there are large amounts of information daily that require much time, effort, and know-how to verify their accuracy. In this chapter, a DPYD game which can be used with the relevant teaching units of the Project P.A.T.H.S. is introduced so as to strengthen the cognitive competence of adolescents. Some practical and design issues which deserve our concern will be illustrated step by step.

For the preparation of materials, the instructor may read and familiarize themselves with the cognitive traps categories and the corresponding examples. It is believed that providing

some real-life examples for each category may help make the class discussion more interesting.

In order to motivate students, the instructor may initiate the thinking process by asking the class, “What is the purpose of identifying the cognitive traps? How do cognitive traps relate to our daily lives?” On top of that, the instructor may guide the class to first expand their understanding of cognitive traps before answering the questions.

In introducing the game and in discussion, the six primary thinking principles which help students think critically will be introduced. Students are encouraged to recite the principles to each other. After that, the instructor may explain to the students: There are 51 cognitive traps in the entire game, which includes 17 traps in each of the Challenge Zone 1, 2 and 3. During the beginner stage (Zone 1), only the first 17 cognitive traps will be discussed and tested. There are three checkpoints within each challenge zone, being 1-Star (Easy), 2-Star (Normal), and 3-Star (Hard). All the topics in 1-Star are to be completed during class; students are advised to thoroughly familiarize themselves with the definition of the cognitive traps in order to complete the remaining topics in 2-Star and 3-Star after class. To maximize the benefit of the game, it is advisable for students to continue playing the game in their free time in order to understand and be able to recognize the 51 types of traps in their daily lives.

For the purpose of creating interest and involvement, the instructor may add, “Would the protagonist eventually come to his senses? How would the story end? Find it out by completing the game!” Students may devote their full efforts into the game and maximize their learning when they find it interesting.

Upon completion of the game, the instructor may inspire discussion by asking the class, “What did the protagonist use to banish the spider in the game?”, “Is being good at thinking equivalent to putting the thinking ability in good use?” A relaxing and interactive learning environment should be provided for students for personal reflection.

Furthermore, the attitude of learning cognitive traps can be discussed. At the end of the game, the protagonist is pleased with himself for comprehending the Thinking Principles as he waves the “Thinking sword” in the air to flaunt his proficiency in thinking. Regarding this scenario, the instructor can ask “Do you agree with the protagonist’s attitude? What sort of problems would surface if one simply has the “technicality” of thinking without “sensibility” and a sense of justice? Is it important to use thinking skills well? Are you willing to help others with your thinking skills?” It helps students understand that using the “Thinking Sword” as a weapon to humiliate others’ thinking fallacies or misjudgments taints the beauty of thinking.

Besides, other reflection questions about their learning for future application can be discussed. For instance, “How can the computer game be of use to you in recognizing cognitive traps in the future in your daily life? How will you utilize the knowledge and skills you have learnt in class in your daily life? Why should we beware of cognitive traps in our daily lives?” These questions help conceptualize students’ learning for their actual application.

In the following part, several supplementary activity suggestions will be provided. First, the instructor can invite students to share their learning and feelings for the day. The instructor may respond according to students’ sharing and offer encouragement so as to strengthen their learning outcome.

Second, a “Cognitive Traps Questionnaire Design Competition” can be held. Instructors may co-host the competition with the Student Council in order to devise new questions on cognitive traps that are not mentioned in the game. Since most cognitive traps categories and

definitions are referenced from a book called “The Art of Thinking Clearly” by Dobelli [51], instructors are suggested to refer to the book when devising new questions on cognitive traps.

Third, it is suggested to organize an event called “Name the Cognitive Traps.” Instructors can co-host this activity with the Chinese Society, for the purpose of amending the names of the existing 51 cognitive traps and/or naming new ones that are not mentioned in the game. Participants are asked to refer to and name the cognitive traps that are mentioned in the book *Why do we always believe we are right? 101 Common types of unconscious cognitive traps*. It allows participants to understand the differences between the actual proverbs and their respective definition as cognitive traps.

Fourth, it is proposed to hold a “Thinking Sword Competition.” The competition can be co-hosted with the Student Council or other student bodies (e.g., The Debate Society) to assess students’ abilities to recognize cognitive traps and expand their existing knowledge. Students are allowed to devise the rules for the competition. Besides, they may use the submissions from the “Cognitive Traps Questionnaire Design Competition” as the theme of the competition.

During the learning process, it is crucial for students to acknowledge that being able to identify cognitive traps do not give them a right to be arrogant or dominate others with their thinking. Besides, they should be kind and logical when attempting to point out others’ thinking fallacies to avoid denigration. They need to learn to accept that they are susceptible to thinking fallacies, have the integrity to admit mistakes, and be open-minded to others’ perspectives. Moreover, they should not judge others mindlessly, or disagree for the sake of disagreeing, but learn to respect others’ beliefs and values. Furthermore, they should be empathetic, and be considerate to other’s difficulties with thinking fallacies. A sense of “chivalry” should be cultivated, which means that they should not be boastful, give more, expect less, and use their thinking skills to be of service to others.

ACKNOWLEDGMENTS

The design and production of the seven digital games introduced in this book, the preparation of this work, and the Project P.A.T.H.S. were financially supported by *The Hong Kong Jockey Club Charities Trust*. Readers may request free copies for non-commercial purposes of these games by contacting Dr. TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This chapter is based with permission on a paper adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

ABSTRACT

Growing up through adolescence is like travelling in a journey which is full of wonder, excitement, fun, and often frustrations, sadness and sometimes adversities. With this analogy, a digital positive youth development game, targeting users aged 12-17 to promote self-understanding, gender- awareness and equality, friendship, and romantic relationship is designed and developed in English, Traditional and Simplified Chinese. It is free for non-commercial purposes and can be used as an electronic learning resource for psycho-social sex education. This chapter presents the design and functions of the different components of the game after a brief review of the literature on the core positive youth development constructs and their connections with friendship and romantic relationship. Practical issues are discussed.

* Corresponding Author's Email: sarahlee@hkbu.edu.hk.

INTRODUCTION

The psycho-social approach of human development postulates individuals must go through the developmental struggle between their capacities and own traits and various demands of the environment. This approach has solid linkages to theories of evolution, psychosexual development, cognitive development, learning, social role, as well as cultural theory and systems theory which explain and predict adolescent development. Recent efforts in the advancement of human development theories are shown partly in the integration of the fulfilment theories into the field of positive psychology [1]. Recent trends of research in positive youth development (PYD) inform prevention programs for adolescents. Based on research findings on evaluations of PYD programs, Catalano et al. identified 15 PYD constructs among successful programs. They are social (SC), emotional (EC), moral (MC), cognitive (CC), behavioral competencies (BC) which can be regarded as core competences. Moreover, they also include clear and positive identity (ID), beliefs in the future (BF), self-determination (SD), and self-efficacy (SE) [2]. These four constructs require a solid foundation of the five core competences. Furthermore, to facilitate positive development, adolescents need to strengthen their capacities on bonding (BO), resilience (RE), spirituality (SP), prosocial norms (PN), and engage in prosocial involvement (PI). Last but not least, recognition for positive behavior (RB) helps to reinforce the development of all other constructs. The Project P.A.T.H.S., designed to strengthen these constructs, has demonstrated encouraging evidence and been recognized as an effective preventive program [2-6]. The Project received support to revamp its program by providing themes to tackle common adolescent issues which include education for anti-drug (AD), anti-bullying (AB), Internet use (IT), money and success (MS), and sex education (SX).

In Hong Kong, most secondary students do not have many opportunities to receive sex education, particularly from the psycho-social perspective [7]. To fill this gap, a total of 15 curriculum units (five for each year for grade 7 to grade 9) on sex education are included in the extension phase of Project P.A.T.H.S. Sex education is intended for personal growth in which students have the chance to reflect on self, gender differences, relationships, love, dating, and diversity. With the support from the sponsor, a digital positive youth development (DPYD) game is designed to promote friendship and romantic relationship (FRR) to support sex education. In this game, all constructs are included except three—promotion of beliefs in the future, providing opportunities for prosocial involvement (PI), and recognition for positive behavior (RP).

LITERATURE REVIEW

Strengthening of Social Competence

Baron [8] defined social competence as an individual's capacity to interact with others appropriately and effectively. Reed [9] proposed that social competence contains two major components, which include 1) organizing cognitions and behaviors into actions according to a socially acceptable aim, and 2) assessing and modifying one's social behavior in a socially acceptable way. According to Agir [10], the level of social competence is positively

associated with an individual's emotional management skills. Aside from these, perceived social competence is negatively related to social exclusion [10]. These show that a high level of social competence will bring positive outcomes to adolescents which are essential for them to build harmonious and mutually-constructive FRRs. This game is designed to promote social competence through many short stories from Chinese and Western cultures. Short quizzes are provided to ensure players to clarify their own values, and to master knowledge and skills necessary for building up and maintaining FRRs.

Enhancement of Cognitive Competence

There are two essential elements for constructing cognitive competence. The first form is "the ability to develop and apply the cognitive skills of self-talk, the reading and interpretation of social cues, using steps for problem-solving and decision-making, understanding the perspective of others, understanding behavioral norms, a positive attitude toward life, and self-awareness" and the second aspect is "the ability to use logical and analytical thinking, and abstract reasoning which directly contribute to academic and intellectual achievement" [11, p. 136]. Resonating with the "cognitive processes" proposed by Fry [12] in which one would be able to think critically and apply the knowledge learnt into practice, cognitive competence supports individual's "overt behaviors" such as problem-solving skills and decision-making [13]. High level of cognitive competence is found to bring a number of positive outcomes to youth development: 1) prediction of better academic performance at school, 2) improvement in physical health due to outstanding problem-solving skills, 3) lower tendency of aversive behavioral problems, including bullying, violence and drug abuse, 4) reduction of mental or emotional illness, such as depression and anxiety, 5) cultivation of leadership skills, and 6) stimulation of critical and creative thinking [14, 15]. Owing to the fact that cognitive competence is the core stone of all action and behaviors, it is of utmost importance for adolescents to develop such competence from a young age. The game is designed to enhance players' FRRs via the enhancement of cognitive competence through the teaching of literature.

Fostering Emotional Competence

Boyatzis, Goleman and Rhee [16] defined emotional competence (EC) as "a person demonstrates the competencies that constitute self-awareness, self-management, social awareness, and social skills at appropriate times and ways in sufficient frequency to be effective in the situation" [17, p. 2], which could be acquired through social interaction and cultural experiences with others [17]. Lau [18], quoted from Saarni [19], concludes three core elements in the construction of emotional competence, which are "the skills for identifying personal feelings and those of others, the skills for communicating emotions with others, and the skills for coping with negative emotions and adversities" (p. 357). Adolescents with good emotional competence showcase a positive relationship with their well-being and development. Proper emotional management has a higher chance in preventing adolescents' alcohol, drugs, and mental problems such as depression, stress and anxiety [17]. College

students who score high in emotional intelligence are more likely to report positive relationships with parents and friends [20]. Young people's ability to handle negative emotions and pressure would be strengthened through proper expression and coping strategies [17, 21]. The game design makes use of a large amount of Chinese and English literature to enhance players' empathy and stimulate perspective-taking to enable them to be absorbed into the stories and understand others' emotions to enhance their emotional competence and subsequently their FRRs.

Building Behavioral Competence

Ma [22] proposed that behavioral competence is determined by four components. 1) Moral and social knowledge: imitation and the following of the learnt "social norms, common manners and rituals, social laws, rules, and regulations in an organization or group"; 2) Social skills: manipulation of verbal (oral expression and writing) and non-verbal strategies (facial expression, gesture, tone of voice and eye contact); 3) Positive characters and traits: positive character qualities such as endurance, patience and conscience help promote one's well-being and moral behavior, for instance, respect, responsibility and reciprocity; and 4) Behavioral decision process and action taking: involving the identification and interpretation of the problem, formulation of a moral and ideal plan, evaluation and assessment of the consequences of the action, and implementation [22, p. 88]. Behavioral competence is the result of all other forms of competence, in which cognitive competence enhances students' intelligence, providing sufficient information for one to identify problems and think of possible solutions; emotional competence reminds them to think twice and avoid being impulsive before the actual implementation. This ensures youngsters to make the correct decision, which would generate positive and proper outcomes. The game provides clear guidance and suggestions for players when encountering a range of dilemma or difficulties – from the appropriate physical boundaries for getting along with the opposite sex to the proper ways to end an intimate relationship.

Enhancement of Moral Competence

Moral judgment competence is defined by Kohlberg [23] as "the capacity to make decisions and judgments which are moral (i.e., based on internal principles) and to act in accordance with such judgments" [23, p. 425]. It means that people show their moral competence by only considering if the arguments are in line with their moral principles instead of their personal desires [24]. Thus, it is expected that students with a higher level of moral competence will be less influenced by the unconscious biases in moral judgement based on peer norms, and hence moral competence is negatively associated with the likelihood of a student's conforming the bullying behavior of his/her peers [24]. Besides, Lajčiaková [25] found that the level of moral competence is positively correlated with both cognitive and affective empathy. The game provides rich contents and many scenarios to encourage players to apply knowledge and skills in making rational and moral decisions when handling FRR issues.

From the holistic perspective, the other 10 PYD constructs identified by Catalano [2] among successful programs are also closely related to how well adolescents build and maintain FRRs. For instance, bonding (BO) with friends and adults in society [26] such as school and church is a protective factor for sex behavior among male adolescents [27]. Prosocial activities (PN) and peer values are protective factors for adolescents against sexual behavior [28].

The Project P.A.T.H.S. which aims to bring positive changes in all PYD constructs has produced promising results by a longitudinal study [25]. It is found that significant differences were shown in clear and positive identity (ID), self-determination (SD), self-efficacy (SE), resilience (RE) and spirituality (SP) among students who joined the program, indicating that they had great improvement in these constructs [6]. Besides, improvement is also shown in bonding (BO) and prosocial norms (PN) among students who participated in the program even though the differences were not significant [6]. During the second phase of its implementation in 2009-2012, the research team revamped some of the curriculum units to offer sex education as one of the six adolescent issues. The research team added some electronic materials to meet the needs of teachers and students in 2018. The DPYD game introduced in this chapter is one example.

Learning about Romantic Relationships in Sex Education

In most modern urban cities around the globe, adolescents have resources and capacities to learn about romantic relationships. In some extreme cases, children at the age of 10 might have experienced intimate sexual behaviors and breakups. Many sex education programs have been developed to address related issues. From the psycho-social perspective, it is advisable to help early adolescents to build up and maintain good friendships before they engage in romantic relationships.

From the preventive perspective, a comprehensive school-based sex education program which aims at boosting protective factors instead of only dealing with the problematic students or weakening the risk factors is more convincing [7]. To facilitate the achievement of the goal of prevention through PYD, a digital PYD game is developed to help adolescents to learn their developmental needs from various aspects such as friendship, and boost their social, moral, cognitive, emotional, behavioral skills, and related PYD constructs [7]. Throughout the game, a life-skills-based education is adopted and players are given sufficient opportunities to express their views in a relaxing way so as to encourage their personal thinking and boosting their strengths. Thus, it can facilitate adolescents to enhance their protective factors and prevent them from committing risky behaviors in FRRs. Table 1 shows the aims and learning targets of the original teaching units for the promotion of bonding with peers and relevant contents in the digital game.

Specifically, the contents of the digital game are closely related to 8 out of 15 revamped units. Table 2 shows the aims and learning targets of these 8 units.

Game Design and Function: Station 1

This DPYD game is designed for adolescents aged 12-17 to foster self-understanding, gender-awareness, friendship, and romantic relationship. It started with enhancing students' self-awareness and self-image by providing positive feedback to their responses. Then, the game enhances students' awareness of gender equality and gender sensitivity before they are introduced to rich educational contents on FRRs.

Self-Understanding

Self-understanding, a composite of different aspects in regulating oneself, leads to the development of emotional intelligence [29]. Self-awareness, defined as being aware of the internal states and their interactions or relationships to others [30], is generally associated with positive psychological well-being and is crucial for one's healthy psychosocial development. If one feels inadequate compared with peers, they may avoid learning new things or stepping out of the comfort zone [31]. Moreover, a weak self-concept may lead to difficulties in peer relations [32].

Game Design and Function: Station 2

One hundred pieces of artwork on traits are used -- 43 positive, 43 negative, and 14 neutral images. Traits include lively, stupid, fair, proud, friendly, idealistic, filial piety, reliable, depressed, kind-hearted, serious, principled, intelligent, hypocritical, feeling inferior, unruly, shy, contented, cynical, timorous, bored, naïve, going with the flow, ambitious, witty, impatient, desired to advance, nit-picking, passionate, nervous, greedy, etc. [33]. A five-point Likert scale is used (exactly like me, very similar to me, quite similar to me, not quite like me, completely different from me). Feedback will be given according to responses. This part of the game can serve the purposes of engagement, initial assessment, and treatment planning for enhancing players' self-awareness and self-image that are necessary for the promotion of a positive identity [34]. This DPYD game provides positive feedback or encouragement to those who choose a positive or a negative trait respectively. A side game is provided to ask the players to select some from among the negative traits for a change. Instructors may use this part of the game to help adolescents who encounter difficulties in FRRs for secondary prevention.

Gender Awareness

A gender stereotype is composed of beliefs about traits and characteristics of, and role appropriate behaviors of men or women. It forms one's prejudiced attitude and as a result discriminative behavior [35]. Even the two genders have their specific roles, the differences have become blurred as time changes, and the traditional stereotypical roles have evolved towards equality. Socialization to a large extent determines one's awareness of gender equality [36]. Bandura's social cognitive theory is used to explain gender development and functioning [37]. Gender-sensitivity is vital for clarifying confusing gender expectations as well as building and maintaining reasonable and stable heterosexual intimate relationships [35].

Table 1. Aims and learning targets of the original teaching units

Teaching Unit Code and Name	Unit Aim	Learning Targets	PYD	Relevant contents in the Game
BO1.2 “The Power of Personality”	To enhance students’ understanding of their own personality and to investigate the effect of personality on interpersonal relationships	1. To learn about three major types of personality 2. To understand the effect of personality on interpersonal relationships	BO	Station 1: Self-understanding; Station 6: Enneagram
BO1.3 “Looking for Friends at the Crossroads”	1. How to recognize desirable friends from undesirable ones and encourage students to choose the right friends and establish a healthy relationship 2. To show the required skills to resist temptation	1. To identify the determinants for desirable and undesirable friends 2. To practice refusal principles and skills	BO, SC	Station 3: Desirable and undesirable friends; becoming a good friend; Station 4: Seven levels of friendship;
BO1.4 “Sail on Together”	To establish trust among students	1. To understand the importance of trust in friendships 2. To practice skills that establish or promote trust between classmates	BO	Station 4: Seven levels of friendship; Station 6: 14 core friendship components
BO3.1 “Modern Love Stories”	To understand qualities of a healthy love relationship	1. To examine one’s attitude toward love relationship 2. To identify the essential elements of love	BO	Station 6: Core components of FRR
BO3.2 “What is Freedom of Love?”	To construct the proper attitude toward love relationships	1. To differentiate the proper and improper attitudes that appear during the initial stage of love relationships 2. To generalize the do’s and don’ts of dating	BO	Station 2: Gender biases; Station 5: love or like? Station 7: “The Love Institute”

Table 2. Special teaching units for sex education and relevant contents in the game

Unit Code and Name	Unit Aim	Learning Targets	PYD	Relevant game contents
ID1.3/SX1.1 “Golden Youth”	To understand and to learn how to go through the physical and psychological changes of adolescence	1. To understand that adolescent development varies from person to person, and that we should not make comparisons or ridicule others for how they are changing 2. To understand what leads to these changes and learn to face them positively	ID, SC, EC	Station 1: Self-understanding Station 3: gender biases;
BC1.1/SX1.2 “Close Relation-ships?”	To understand that opposite-sex and same-sex friendships require different attitudes	1. To understand that excessive intimacy with the opposite sex may lead to misunderstandings 2. To learn about appropriate physical boundaries for getting along with the opposite-sex	BC, BO, EC	Station 2: gender biases; Station 5: love or like? Station 7: “The Love Institute”
PN1.1/SX1.3 “Sex and love”	To understand the meaning of sex and love	1. To understand the definition of sex and how it is related to everyday living; 2. To learn to respect and consider other people’s feelings before deciding sexual behavior 3. To understand the consequences and responsibilities after sexual behavior	PN, BC, SD	Respect; legal and moral consequences of intimate behaviors; Station 7: “The Love Institute”
ID 1.2/SX1.4 “Sex and Peer Pressure”	To understand how friends affect our decision making and behavior	1. To know how peer pressure affects our decisions and behavior 2. To think about the motives and attitudes before we face sexual behavior	ID, BO	Station 1: Enhancement of self-understanding Station 3: Peer pressure
SC2.1/SX2.2 “Men...Women...Not”	To understand gender roles	1. To understand gender stereotypes 2. To understand views and values on gender roles	SC, PN	Station 2: Clarification of gender stereotypes
MC2.1/SX2.3 “You can’t be good at this”	To understand sex equality and discrimination	1. To understand how stereotyping affects career decisions 2. To learn the importance of gender equality	MC, SD	Station 2: Promotion of gender equality
BO3.1/SX3.4 “Marriage... before and after”	To examine the relationships among family, marriage and sex	1. To understand the similarities and differences between dating relationship and marriage 2. To clarify one’s values on sexual relationship in dating or before marriage	BO	Station 7: “The Love Institute” -- dating relationship
RE3.4/SX3.5 “Happy ‘Never’ After”	To cultivate positive views on marriage	1. To know the factors contributing to happy marriages and those to divorces 2. To find out how one could be affected by the marriage of parents or close family members	RE	Station 7: “The Love Institute” -- 7 stages of love relationship

Game Design and Function: Station 3

To test players' awareness of gender equality, a twenty-six item scale was used [38]. Sample items include "The gender division of labor at home should be 'men are breadwinners, women are homemakers'"; "Boys are careless, casual, and sloppy. They do not like tidiness or dressing up"; "Girls are always narrow-minded and easy to lose their temper." Immediate feedback is provided to promote gender awareness, clarify gender biases, and promote gender equality. To encourage replaying the game for better learning outcomes, only 10 items are randomly generated. Players are encouraged to be aware of some gender stereotypes and prejudices.

Beneficial and Harmful Friends

There are different kinds of friendships. Children experience different interactions with their peers which include peer acceptance and rejection [39]. A friend can be unique and irreplaceable. However, adolescents may encounter harmful friends. Some friendships can be sustained even when the interactions between both parties cannot generate reward for their development [40]. In other words, friendships, ordinarily speaking, should not be calculative on the cost to the relationship, and people may not expect the other party reciprocate equal effort or favors given. Moreover, young adults differentiate best friends, ordinary friends, and acquaintance by intenseness and intimacy [41].

Game Design and Function: Station 4

Ten interesting questions on how well players treat their friends are adopted to stimulate players' awareness of the quality of interactions and relationships with their friends [33]. Subsequently, short stories on five themes about friendship from Chinese literature are presented with short quizzes to enhance their knowledge. They are "learning alone without friends," "friendship in the East and West," "three types of beneficial friends and three types of harmful friends," "emphasis on loyalty and faithfulness," and "acquaintances all over the world but few bosom friends." Two questions will be randomly generated from a pool of five questions in each theme. Players will have to answer the two questions correctly at the same time before they are allowed to move on to the next stage of the game.

Friendship

The term "friend" has many different meanings when it is referred to a range of relationships. Friendship can be classified into 4 levels which include acquaintance, casual friends, close friends, and intimate friends. Acquaintance and casual friends are friendships, in which both parties do not engage deeply. Both parties may have little knowledge about each other. The difference between an acquaintance and a casual friend may be the number of interactions. Close and intimate friendships can only be formed when both parties make an effort to know each other. People regarded that there are different behavioral strategies for maintaining close and good friends [42]. A good friendship is regarded as more self-maintaining, more dependent on affection, which in turn is less reliant on proximity than casual friendships [40, 43].

Game Design and Function: Station 5

Using the analogy of mountaineering with a close friend, the game design adopts a more sophisticated classification system to differentiate friends into seven levels: massive crowds, followers, acquaintances, casual friends, good friends, fraternity, and confidant. The following table shows the details.

In the first part, players are asked to respond to a questionnaire [44] and feedback on how the player performs in groups, according to the “System for the Multiple Level observation of groups (SYMLOG)” [44] which will help players understand leadership, group dynamics and working with people in groups. Players will take a short quiz after reading a short article on communication modes. Then, players will be given tips for improving communication. To continue with the game, players will have to take a quiz on each of the six levels after reading short passages from Chinese and Western literature. Having gone through these seven levels, players are enabled to have a deeper understanding on the meanings of friendship.

Table 3. The contents of station 4 “Friendship Mountain”

Checkpoint	Contents	Equipment for Climbers
Massive Crowds Peak	Knowing the characteristics of personality	Peak-climbing guide
Followers Peak	A sincere heart/ Based on interests	Tent
Acquaintance Peak	Helpful friends, harmful friends	Eye mask
Knowing Peak	Four attitudes towards friendship: Empathy, Acceptance of diversity among individuals, Acceptance of diversity in individual intuitions, Adjustment of attitude based on the situation of the other side	Gloves, backpack, hiking boots, chisel
Good Friends Peak	Caring skills	Walkie-talkie
Fraternity Peak	Forming a literary circle	Altimeter
Confidant Peak	A friend until death	Ropes

Love or Like?

Adolescents may not be able to differentiate love from like. However, friendship comes before love. Players are encouraged to reflect on their friendship with a good friend of the opposite gender, and complete Rubin’s Love and Liking Scale [45, 46]. It helps players know more about their feelings and differentiate between romantic love and friendship-based love.

Game Design and Function: Station 6

The story goes like this. Players have arrived at Hazy Moon Station, which is near Hazy Moon Walled Village. Villagers attach great importance to friendship and respect love and marriage. They generally respect young people’s choices for their lovers. However, they still stress family values and attach great importance to the faithfulness of love and relationship in marriage. Villagers disagree that love is a game. They also oppose to learning about love from mistakes. People come to visit this village because of its fame and are attracted by the village’s love education. The game design requires players to take a quiz on their choices of famous Chinese love poems.

Being Watchful

Friendships differ in quality and in intimacy level. Although it is difficult to judge friendship quality by behavior, Davis [47] assesses the quality of FRRs by seven global characteristics. They are (1) viability (including acceptance, tolerance, respect, and trust), (2) intimacy (including confiding and understanding), (3) care (including giving the utmost, championing, and assistance), (4) passion (more in romantic relationship), (5) commitment, (6) satisfaction, and (7) conflict and ambivalence. In this game, the subscales on passion and conflict/ambivalence, the constructs of success, conflict and ambivalence are not adopted due to the age of the game-players. Three facets from the satisfaction subscale, namely enjoyment, reciprocity, and esteem as well as two single facets, maintenance and equality are also used. These 14 constructs are conceptualized as core components of FRRs.

Table 4. The core components of FRRs and the major contents of station 6

Name of Scenic Spot	Core Component of FRR	Major Contents of Station 6
Meditation Sea	Understanding of self and friends	Enneagram
Tianping (Balance) Village	Equality	Discussing gender equality in ancient poems
Comfort Forest	Pleasure	Confucius' three types of harmful and disadvantageous pleasures
Patience Mountain	Acceptance/ tolerance	Foundations for maintaining a relationship
Dedication Spring	Devotion	Respect, understanding, caring, and being responsible are 'giving' behaviors.
Thousand-hand Cliff	Assistance	Active and passive helping; rejecting unreasonable requests
Heart-to-heart Lake	Trust	Keeping one's promises is the first step for building up trust.
Respect Lake	Respect	Benevolent people love others while polite people respect others.
Fidelity Rock	Loyalty	With the freedom to love, 'whom do I love the most' is a difficult question.
Awakening Rock	Self-esteem	Building up one's confidence and personality
Symbiotic Wood	Reciprocity	FRR depends partly on mutual benefit.
Jintang (Golden hot water) Brook	Championing	Love is harder than gold.
Xique (Magpie) Bridge	Maintenance	Maintenance of FRRs
Echo Valley	Confiding	Confiding to others and active listening

Game Design and Function: Station 7

Using the analogy of a journey, scenic spots are named after the 14 core components. Each spot provides both Chinese and English short stories with short quizzes. Some side games are also provided to attract players. One example is to compose melodies through choosing from four musical instruments and using just three notes (Do Re Me) to create different pieces of music. Immediate playback is available.

The Love Institute

A number of questions are raised to motivate students to play this game.

- Do you believe that real love is not momentary, but long-lasting instead?

- Have you ever witnessed your friend feel frustrated due to the failure of first love?
- Have you ever found the frustrations from first love in books or movies?
- Have you ever experienced failure in your first love?
- Have you ever questioned why the simplest, yet the most captivating and mesmerizing first love is frequently fragile and temporary?
- Is experiencing obstacles in one's first love a necessary stage in life?
- Are the frustrations experienced in one's first love related to one's behavioral and emotional characteristics? Is it inevitable?

As an introduction, students are guided to read the following statement: "This Institute has always emphasized the importance of social and emotional education for families, friends and couples. In light of the current over-emphasis on academic results, we started this Institute to provide short-term courses for people interested in more fulfilling relationships. We believe you are attracted to this place because you may want to have a deeper understanding of love and gender equality in Balance Village and to know the reasons for the zero separation/divorce rate among villagers."

The material goes on to provide further guidance: "When we are nourished by love, we feel sweet and happy. However, differences between people begin to surface as we gradually enter into each other's lives. Differences in lifestyle habits, needs, beliefs, and values may catalyze conflicts, making them an integral part of the path to love. Learning to work with each other while going through conflicts allows the relationship to become more intimate so that both parties may travel on the path of love together!"

Students are given a full list of choices in a chart. It states "The Institute offers two majors, being (A) To Commit; (B) To Breakup. You must first make a choice. The prerequisites for both majors are three compulsory subjects, being (1) Observation; (2) Gestation; (3) Disclosure. After that, students may choose one elective in Stage 4 (Romantic Period) and Stage 5 (Conflict Period). Finally, a student may choose one major from two (either to commit or to breakup) and go through Stages 6 and 7. A total of seven subjects must be completed to graduate."

After Stage 5 (Conflict Period), students are required to make a choice of either to commit or to break up. No matter which direction students choose, they are offered two more stages. Courses offered in Stages 6 and 7 represent two separate routes. For commitment, there will be Stage 6A – The Understanding Period, and Stage 7A – Recommitment. For breakup, there will be Stage 6B – The Breakup Struggle, and Stage 7B – The Breakup.

Contents of the Love Institute

The courses comprise of both compulsory and elective parts, classified into seven stages summarized by Fok [48] who is a very experienced family therapist. Students must commence from Stage 1. Users are required to go through the seven stages of romantic love with two different endings (majors) – to commit or to separate. As a gimmick, they are told that there is no course exemption or credit transfer.

Different educational and motivational strategies are used to increase the attractiveness of the lengthy contents. Some are presented through short passages, questions and answers. Case

discussions are used to stimulate further thinking. Validated psychological tests and interactive tests are used to provide individual feedback. Short tests with feedback based on knowledge of social sciences are also offered.

The courses in the first three stages are compulsory. Users are not offered choices.

1. **Observation period:** Developing feelings for each other -- a case discussion on developing a relationship with an Internet “friend” [49].
2. **Gestation period:** Increasing the frequency of contact with each other -- an adaptive interactive test with only 7 questions named “Will my relationship with her/him be fruitful?” [50, pp. 31-32]. Three different types of feedback will be provided according to the responses of students.
3. **Disclosure period:** Directly revealing feelings to each other -- a short passage reminding students of respect, equality, responsibility, allowing each other space, putting in effort and dedication in the relationship as well as to minimize misunderstanding and hurtful feelings.

Stages 4 and 5 offer “common electives” representing different experiences everyone may go through. Students can choose one among the three (Stage 4) and six (Stage 5) courses.

4. **Romantic period:** Missing each other day and night; being together like the honey and the bee; trying hard to show one’s best side; mutual attraction. A sweet romantic period makes people radiant and energetic. A turbulent conflict diminishes people’s passion. The vast contrast between the two makes it difficult for people to adapt. Students may even doubt love and fabricate illusions – causing irrational thinking. Students may choose one from the following three common electives.
 - a. **Interesting tests for male and female students**

Checking honesty, respect, integrity, and unselfishness. For male students: Am I a frog or a prince? [50, pp. 74-75]. For female students: Is he a frog or a prince? [50, pp. 92-93]. Before taking the test, 12 commonly found lies by males are presented and they remind students that these words (lies) are usually used by men to take advantage of women. It serves as a starting point to go through the quiz.
 - b. **Does love equal a yearning for passion?**

It provides a short passage to help students differentiate yearning for passion and love [48]. On the other hand, lyrics from a popular song are used to remind students that physical distance entails anticipation and surprise.
 - c. **Love language**

Chapman’s [51] conceptualization of five love languages, i.e., affirmation, quality time, receiving gifts, acts of service, and physical touch is introduced. Thirty pairs of sentences are given to test participants’ choices in order to calculate and show their comparative reliance on certain types of expression of love. Definitions and guidance notes on each love language are provided.
5. **Conflict period:** As important and commonly found experiences among lovers, this stage introduces issues of decreasing in passion and resolving discrepancies with each other. Six choices in the name of common elective courses are provided.

a. **You love me, don't you?**

It is about emotional blackmail between adolescents in a love relationship. Pathological and suffocating ways of getting along are presented [52]. They are important contents which are seldom found in formal educational curriculum. They are provided to help prevent adolescent relationship issues from deteriorating to pathological problems.

b. **I have feelings for another person, am I a fool?**

The major difference between romantic love and friendship is the excludability in romantic relationships. Clarifications are made between the two. Reasons are provided [48, p. 178].

c. **A fine line between love and hate?**

Talking about love, one often thinks of positive, beautiful and warm scenes. People often quote the book of 1 Corinthians Chapter 13 Verses 4-8 from the Bible in describing love. However, what is commonly found is the opposite. Tao [53] offers an interesting reversed version which serves as a good reminder for all people in love relationships.

d. **Sources of conflicts**

e. Five types of conflict resolution proposed by Kilmann and Thomas [54] are used to design a short test with eight questions to differentiate one's commonly used ways of handling conflicts. Advantages and disadvantages of each type are provided [33, pp. 104-109].

f. **Ten commandments of conflicts**

Wong's [33, pp. 110-111] ten inappropriate behaviors to avoid are presented to remind lovers how to behave in conflict with people they love.

g. **Ten ways to intensify conflicts**

Adapted from Osborn, Hunt, and Jauch [55], Lee's [56] ten ways of heightening conflicts serve as another interesting way to remind them how to behave in conflict.

By now users are required to choose either "to commit" or "to separate." Each choice offers two stages. For commitment, they are 6A "understanding" and 7A "recommitment." For separation, they are 6B "struggling to break up" and 7B "breaking up."

6B3. Understanding period: It covers how to get a deeper understanding and be more caring and intimate with each other during and/or after conflicts. Four choices, each on one key issue, are provided. They are:

6A1. The fragility of first love – Philosophical notes on "The Little Prince"!

Originally written by Antoine de Saint-Exupery, Katherine Woods' [57] translated version of *The Little Prince* and Chow's [58] philosophical notes are chosen to provide an in-depth understanding of the complicated issues around romantic love. To enhance users' comprehensive understanding of related issues, lengthy contents are provided through questions and answers. Interesting and inspiring questions are raised and thoughtful answers are given. Ten major questions include: Is this the so-called "happiness" we are striving for in our romantic relationship? Why was the Little Prince so determined to leave the rose

and let his beloved rose live on the asteroid alone? What problems arose between the Little Prince and the rose that contributed to his departure? At the moment of farewell, what was deep inside rose's heart? Why did the Little Prince have this kind of reaction after seeing the 5000 roses? What does "taming" mean according to the fox? What did the fox want to tell the Little Prince? If the Little Prince did not leave the planet, would he have had such an insight? Are we the rose? How do we find a person to tame in our lives, and how do we live out a tamed relationship?

The book is chosen because of its relevance of its contents to the message we want to get across. It is also the most-translated book (into over 250 languages) among all French novels. Chow's [58] philosophical notes provide an insightful and fruitful discussion on issues of romantic love relationship as well as a sensible guide for everyone who wants to understand romantic love. This section is the lengthiest among all in this educational material. It has about 3,500 words and 10 important questions.

6A4. Love and forgiveness

A short passage by Wu [59] on forgiveness in love relationship is given. Users from different cultural backgrounds may have difficulties in forgiving or have been socialized to be gentle and suppressive in power relationships. The message is that forgiveness does not mean staying silent to avoid conflicts, bowing to please others continuously, or hiding discontent or even feeling guilty of being angry. Disregarding the problems not only prolongs the underlying issues in relationships but intensify them as well. When both parties are fed up with each other, conflicts explode. In contrast, expressing feelings to each other assertively can improve mutual understanding.

6A3. Who's right and who's wrong?

To protect one's own pride, when conflict explodes in a couple's relationship, one would often say to the other, "It's all your fault!" A short passage on how to handle interpersonal conflict in words with appropriate attitude is provided [60].

6A4. How to handle temporary separation?

Separation is rather common in many love stories. Failing to deal with it appropriately may cause guilt and regret that can last a lifetime. One common scenario is when the two are still students, and one party is sent abroad to continue with her/his studies after they have been dating for a while, which usually leaves them feeling helpless despite the availability of instant message and social media. According to Fok [48], there is an important reminder for young people in romantic relationships: when the relationship is not fully developed yet and the pair is in separation for over two to three years, this would definitely hinder the development of their relationship. Therefore, before separation, they must have enough time to communicate with each other in order to avoid traumatic feelings, such as abandonment, betrayal, deception and suspicion, or the sense of being stuck in a dilemma.

- 6A. **The breakup struggle:** If conflicts cannot be resolved, there will be much pressure within the relationship. Struggling on the decision to break up may not be difficult for some but how to break up sensibly and responsibly?

6B1. Breaking up with your partner

A case on a pair of young lovers struggling to break up is described [49, pp. 164-169]. Questions include: How do you interpret her behavior and motives? How would you use the information you have read to analyze the development of their relationship? If you know her, how would you help her? If you know her 'boyfriend', what advice would you give him?

6B2. Are people who broke off all fools?

Intimate relationships make people feel cherished and sweet. Yet it is the most vulnerable at the same time. An intimate relationship is an expression of valued importance and love. When couples break up, they believe they are not loved anymore, which makes them doubt if there will ever be anyone else to love them again. They are afraid of being abandoned and rejected, and the feeling of not being important anymore is the most terrifying thought that leaves many people perplexed and confused. Furthermore, separation elicits fears in human beings. Young people and particularly those who are serious in an intimate relationship often get hurt in breaking up.

A short passage by Fok [48] is provided to guide users on how to handle the complicated and very often hurtful feelings arising from separation. When breaking up, adolescents need to learn to respect others and at the same time protect themselves in order to continue one's journey separately.

7A. **Recommitment:** Three choices, each on one key issue, are given. They are:

7A1. What are regular reviews and assessments?

A love relationship has its own big and small cycles, ups and downs. Adapting and accommodating to each other in down periods does not necessarily imply the sacrifice of love. On the contrary, if both continue to hide the potential difficulties, the relationship will be at stake and the subjective satisfaction would fluctuate or decline. When the romantic relationship has developed for several years, and there are no apparent or concrete reasons not to get married, many people ambiguously and half-heartedly get married. Because of that, the emotions are set apart upon the marriage. This poses a potential threat to their future relationship. That is why a love relationship needs regular review and evaluation [48, pp. 202-204]. The material provides concrete guidelines on how to review and reflect.

7A2. To recommit or not?

A relationship is a kind of art that is difficult to understand. Marriage throughout the rest of life is significant and precious because it is based on the freedom of choice and voluntary commitment. Based on years of experience with family therapy, Fok [48] offers insightful materials for all – those who are in, or out of, and not yet in an intimate romantic love relationship.

7A3. A mature and intimate relationship

In her book "Intimacy forever," Fok [61] offers insightful discussion on a mature and intimate relationship. To Fok, an intimate relationship is like wrestling. All valuable things have great costs; there is no love without cost. In a romantic relationship, when people still choose to live in this stage, which they can make choices, they should ask themselves seriously: are they willing to bear the responsibility for this person for forty or fifty years? The message in this

section is that love does not necessarily engulf individuals and destroy freedom. On the contrary, genuine love and its richness help us mature.

- 7B. **The breakup:** Preventive and therapeutic guidelines are given in the following three key issues – the pain, the art, and how to prevent emotional harms.

7B1. The pain of breakups

Feelings of being an outcast and abandoned are very difficult to bear. One's self-worth disintegrates as the partner criticizes, judges, and insults. Cultivating inner peace, broad-mindedness and remaining to be calm at all times are all critical factors for attaining spiritual purity. On the other hand, re-evaluating one's values to re-establish his/her faith in humanity that fits the value priorities of objective facts is another important way to reach spiritual serenity. A short passage of Fok [48, pp. 179-182] offers spiritual education that provides food for thought for all users. It serves as value clarification and offers guidance for promoting spiritual serenity.

7B2. The art of breaking-up

This is perhaps the most difficult part. Fok [48, p. 210, pp. 207-208] offers concrete and step-by-step guidelines on how to differentiate clearly with details seven proper ways and five poor treatments.

7B3. How to face emotional harms?

Users are invited to recall an incident that has made them feel very sad and hurt in a relationship. Then, the following questions are raised [62, p. 29]:

1. What adjectives would you use to describe the feelings you had in this incident?
2. What life beliefs have been changed? How did it affect your self-evaluation?
3. How did it affect your relationships with your family members, friends, or even future partners whom you haven't met yet?
4. What have you learned from this incident? How did it help you understand yourself?
5. Did you discover any more important values in your reflection or ways to adjust some life values in an appropriate manner?
6. What was the meaning of this incident to you?
7. After this incident, what are your changes?

On top of these personal questions, a general discussion on why we get emotional harms easily and deeply is simulated. Sensible answers from different perspectives are offered as group discussion results for users' reference. To promote positive development, five tools for improving one's self-image are offered [33].

DISCUSSION

For early adolescents, they experiment to build and make initial and later essential commitments to relationships, from friendship to courtship and then to romantic relationships. All these require their virtue and capabilities to form and maintain effective and constructive

interpersonal relationships. This chapter aims at contributing to the development of psycho-social sex education through introducing a DPYD game that can be used together with the corresponding PYD curriculum of the Project P.A.T.H.S. The effectiveness of the P.A.T.H.S. program in Hong Kong has been recognized by the World Health Organization [4, 5]. Two issues regarding sex education deserve our concern.

Firstly, educators should help adolescents understand FRRs through adopting a positive and holistic view instead of pathological concepts [63]. Many prevention programs on sex education were criticized as focusing only on the biological aspect to reduce teenage pregnancy [7]. Instead, the game can be adopted in the prevention program through PYD.

Second, prevention programs based on a holistic approach have received increasing attention and been generating evidence [2]. It is suggested that the program has to adopt a positive approach to sexuality, create a comfortable atmosphere for interactions and participation, and use a tailor-made syllabus for students and encourage them to express how they think and understand their rights and responsibilities [7]. By using the above measures, students' knowledge about intimacy, love and sex will be enhanced. They will better understand the concepts of gender differences and stereotypes as well as build a positive attitude regarding sex-related issues. According to Fok [64], biological knowledge is one of the protective factors for youth sexual behavior, while having insufficient sex-related psycho-social-legal-cultural knowledge is a risk factor. Providing such knowledge to youth through the above ways is crucial to equip students with a proper attitude towards a romantic relationship. DPYD games have potentials in prevention from a holistic approach of the psycho-social-legal-cultural perspective.

From the practice viewpoint, using different parts of the game can serve the purposes of engagement, initial assessment, and treatment planning for prevention. It can be adopted as a primary prevention program by targeting all adolescents. Besides, the game can be used in secondary prevention for students with some negative self-evaluation or difficulties in FRRs. It acts as a means to strengthen their self-awareness and self-image which are necessary for the promotion of a positive identity. Moreover, the game can be adopted as tertiary prevention which aims at providing intervention to students with serious problems on self-image, gender biases, and serious conflicts in FRRs. At this level, mental health professionals can use relevant parts of the game as an intervention means for individual or group counselling. It helps identify, get an initial assessment, engage with the potential client, and with the player's consent, discuss plans of intervention.

Another practice implication is on the coverage of PYD constructs. It is worth noticing that although the DPYD game design must provide immediate positive feedback and reinforcement of positive responses at the cognitive and intention levels, responses in playing DPYD games are not actual behaviors.

The third practice implication is that young adults can also be the target users. As the contents cover FRRs, the game can be used without adaptation by late adolescents and young adults who experience relationship problems or those who have never gone through formal/informal education on romantic love.

The fourth practice implication is about the special use of the game by students or users in need. This game is designed for use by both adolescents and helping professionals who offer help to students with problems in different stages of romantic love. There are different points of entry. The direct entry to the "Love Institute" can facilitate social and emotional learning on romantic relationships.

For all students, the design encourages them to go through the whole game by visiting all stations one by one. It attracts and encourages students to play the game again as attractive and relevant contents are offered on different routes by having different choices. If students want to learn more about the other choices, or they are keen to know more about romantic love, they may have to go through again from Station 1 to Station 6 in which they explore self-awareness, gender characteristics, ways of getting along with friends, improvement of friendship, identification of love, and guarding their loved one.

The feeling of boredom in reusing this material is largely reduced for two reasons. First, the interactive design provides different feedback according to the responses. Using it repeatedly may enable users to learn more and see the differences resulting from different responses. Second, choices are offered throughout the game, particularly in the “Love Institute.” Users who want to learn more are motivated. Making the best use of a DPYD game depends very much on instructors’ creativity.

With students’ consent, feedback of interactive tests can be copied by using the print-screen key on the keyboard and users may print out the results and/or feedback for discussion between the user in need and the helping professional. The game could be used as an initial assessment tool and it provides comprehensive coverage of key issues for further deliberation.

ACKNOWLEDGMENTS

The design and production of the 7 digital games introduced in this book, the preparation of this work, and the Project P.A.T.H.S. were financially supported by *The Hong Kong Jockey Club Charities Trust*. Readers may request free copies for non-commercial purposes of these games by contacting Dr. TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This chapter is based with permission on a paper adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

ABSTRACT

This chapter offers a brief review of literature on materialism among adolescents and game-based learning on the promotion of one specific positive youth development construct, namely spirituality as a preventive measure. It then describes the design of the digital game and how it can be used as an electronic resource to enhance learning on reflection of materialistic and non-materialistic values and the development of spirituality and enhancement of self-efficacy in financial management. It also provides suggestions on how to use the game effectively. The discussion is supported by in-depth qualitative and critical comments of two users from different cultures and educational levels. Theoretical and practical issues are discussed. Limitations and future research suggestions are presented.

INTRODUCTION

Overemphasis on materialism and high rates of narcissism and overconfidence are some of the common concerns for young people in many developed countries. Most Asian parents believe that their children must enter into a good university so that they will get a good job with high salary. The notion of “hover parents” has been widely accepted by Asian parents. In

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

China, where collectivism is more highly recognized than individualism, similar patterns are observed. In Hong Kong, emphasis on children's high academic achievement seems to have gone to an extreme that parents "should never let their children lose at the starting point" [1-3]. The notion of success held by these parents is rather instrumental and often materialistic. Commission on Youth [4] found that 20-30% of youths would consider using unethical means to achieve what they want which are material orientations based on hedonism, wealth, and sensual stimulation.

When young people value possession and judge success and others by materialistic values, they would consider less on other significant elements of a meaningful life such as moral character and spirituality. They value less in the areas of universalism, benevolence, righteousness, honesty, responsibility, diligence, conformity to norms, cultural tradition, and show less commitment to family, friendship, as well as the community. One plausible explanation is that Hong Kong is a city with strong international connections of finance and trading [5]. However, it is disturbing when a significant number of young people would consider using unethical means to achieve their wealth. Against this background, the promotion of a positive concept of money and success as well as material possession is needed and the production of educational resources for educators, teachers and parents are desirable. With the financial support from The Hong Kong Jockey Club Charities Trust, a digital game designed to enhance adolescents' reflection on materialistic and non-materialistic values was produced.

LITERATURE REVIEW

Materialism is a complex concept with various definitions. From the consumers' perspective, materialism is defined as the desire to pursue goods [6]. Belk [7] equated it with three personality traits which include envy, non-generosity and possessiveness. Shek, Ma and Lin [8] further conceptualized it along three dimensions which include, materialistic possessions, acquisition centrality and hedonistic pursuit and developed a test on materialism in the Chinese culture.

The development of materialism in children and teenagers is complicated. Models are constructed to predict materialism including the consumer socialization model of children [9], materialistic value orientation model and the concept of social comparison [10]. According to John [9], the desire for material goods starts at the early age where pre-schoolers request certain type of products and demonstrate their desires through behaviors such as grabbing and begging. Throughout children's development process, they acquire consumer skills, knowledge, and values that are related to their function as a consumer in the market [9]. The model of materialistic value orientation based on the concept of socialization suggests that materialistic values are derived from experiences with the feelings of insecurity and real life examples of materialistic values, beliefs, and behaviors in children's life [10]. When children's psychological needs are not met, they tend to use material goods to compensate for their negative feelings and sense of insecurity [10]. In addition, the emergence of material possessions among young people is due to a decline in self-esteem when they enter adolescence at the ages of 12 to 13, giving them a strong motivation to obtain material possession to enhance their self-esteem [11]. Chan and Prendergast [12] adjusted the model of

materialistic value orientation and the concept of social comparison by replacing insecurity and materialism exposure with social comparison variables such as family communication, peer influence, peer communication and television viewing as an effort to adapt the model into the Chinese context. The authors further concluded that media figures and social comparison are positive predictors of materialism in the Chinese youth population [12].

Concerns for materialism in adolescent are increasing. Youth materialism, meaning owning luxury goods and the importance of money, has increased over generations of 12th graders in America between 1976 and 2007 due to the popularity of advertising [13]. 95% of adults in American agreed that children are attracted to shopping and about 80% of adults believed that regulations on advertising to children are needed [14]. In the United Kingdom, a phenomenon that parents frequently buy goods for themselves and their children is observed, while such a phenomenon is not found in Spain and Sweden [15]. Interestingly, it was observed that the levels of materialism among children to early adolescence are at the highest and then they decrease afterwards [11]. Comparing children and adolescents with poor and affluent backgrounds, underprivileged children aged between 8 to 10 years old exhibit similar level of materialism as compared to their wealthier peers, but the impoverished teens are more materialistic than their rich fellows when they enter inter adolescence [13].

The perception of materialism is not only found in the west, but also in the east. A study of young consumers in both the United States and China concluded that materialism is cross-cultural as both samples demonstrated similar results in the questionnaire items related to materialism [16]. In another study, Chinese youth tend to be more materialistic when they grow up because of high parental material success expectations due to the one child policy [17], whereas young people in the U.S. reduce their levels of materialism after the peak at early adolescence [11]. Unlike the situation in western countries, television programs have no effect on materialism in children and teenagers because China has restricted rules on media contents [17]. In Hong Kong, adolescents are living in an environment that emphasizes money and material possession. In a metropolitan that focuses on economics and finance, adolescents in Hong Kong develop and maintain their materialistic values [5]. Although Children in Hong Kong do not show an excessive level of materialism, they understand the value of possession as young as six years old [18]. Chan [18] further found that younger children with more pocket money are more materialistic, and the effect of television on materialism depends on the perception on advertisements of children and adolescents.

The concept of materialism is associated with individual's physical and psychological well-being as well as academic performance. A study found that young adults who focus on money, popularity and reputation are more likely to be depressed and report to have experienced physical symptoms such as headaches, sore muscles and backaches [19]. Focusing on money drives individuals to spend more time at work and less time with friends and family, negatively affecting the level of happiness [20]. Psychological needs satisfaction is undermined by materialism, leading to a decrease in psychological well-being and an increase in depressive symptoms [20]. Moreover, those reported with strong materialistic value experience more negative emotions, and thus distanced themselves with positive life constructs which include competence, autonomy, gratitude, and meaning in life [21]. Materialistic youth who have a habit of spending and saving little are more likely to be excited by new products in advertising. They report school as less enjoyable, and have poor academic performance [22].

In order to facilitate positive development in children and adolescents, minimizing the influence of materialism is crucial. In fact, materialism has become a major concern in both developing and developed countries. Scholars suggest some intervention directions to reduce the level of materialism in children and adolescents as improvement in their well-being is observed if the degree of significance of materialistic value and goals decreases [23]. Self-esteem has been proved to be associated with materialism. A study by Liang et al. [24] found that increasing self-esteem results in a low level of materialism and reduced corrupted intention. Meaning in life and psychological well-being are highly correlated in adolescents that meaning in life is a potentially protective factor of materialism [25]. Similarly, another study demonstrated a positive association between meaning in life with well-being, academic adjustment, self-esteem, ethnic belonging and exploration [26]. A normative developmental characteristic during the adolescence period helps the development of spirituality in teenagers, building resilience to challenges in puberty [27]. Chaplin et al. [28] suggested promoting a sense of gratitude in adolescents and children to reduce materialism as those who are grateful with what they have are less materialistic. Based on the previous findings, the design of the digital positive youth development (DPYD) game tackles the aspect of meaning in life to enhance spirituality and promote resilience in adolescents towards materialism.

With increasing recognition of the importance of well-being, many schools promote positive well-being among students on top of the acquisition of skills and knowledge [29]. The digital game described in this chapter is designed to promote one of the positive youth development constructs, namely spirituality. It is intended to promote early adolescents' well-being through reflection on both materialistic and non-materialistic values with game-based learning (GBL). Gaming environment promotes both learning and motivation to learn, allowing students to participate actively in the learning process [30].

As part of the effort in updating teaching and learning materials for the project P.A.T.H.S. [31], a digital game named "Live a meaningful life" was designed and produced in 2015 to support teaching on the construct of spirituality through prudent financial management and reflection on the meaning of life. Digital GBL on financial literacy is popular nowadays due to rapid advancement in information and communication technology (ICT). A study on digital learning game and financial literacy education has found that well-designed and instructionally integrated digital games can motivate players to learn financial management knowledge [32]. In the United States, an online financial game named *Gen i Revolution* (Council for Economic Education) was developed to educate students the importance of personal finance skills [33] for high school students. Over 120,000 students have played the game to acquire knowledge [33]. Other games such as Financial Football and the Visa's Practical Money Skills platform were designed to serve a similar purpose, i.e., teaching children and adolescents about money concept [34]. Our game is designed with a similar purpose for students in Hong Kong, adopting the idea of "Edutainment".

THEORETICAL UNDERPINNINGS OF THE GAME

The name of the game is "Live a meaningful life." It is targeted at Secondary 2 (Grade 7) students. Its design is based on the framework on money literacy for children and adolescents [35] which was inspired by Potter [36] effort on media literacy and research on education on

personal finance and economics as well as the developmental and cultural characteristics of children and adolescents. The framework is built on two levels: foundation and advanced. The former is composed of three components, namely, narrative acquisition, cultivation of traditional value, and developing scepticism. The advanced level consists of experiential exploring, critical appreciation, and social responsibility. The six-stage model [35] covers from developing an awareness of differences between needs and wants to disputing beliefs about materialism and hedonism for the foundation level; and for the advanced level, from searching for gratification and fulfilment from new experiences, which include emotional, moral, aesthetic, and sports activities to recognizing what one can do to contribute to society positively.

Based on the framework, cognitive, affective, value judgement, and behavioral dimensions are covered in the game. For the cognitive dimension, the game covers “desire to gain money”, “money as a symbolic meaning of power”, “cautions in using money”, “money is not the only criterion to determine success or failure”. For the value judgment domain, it includes reflections on whether “money has a symbolic meaning of good or bad” and “personal spending”. On the affective dimension, the game encourages making contributions to support family and society through donations”. Finally, on the behavioral dimension, the game requires players to conduct monthly personal financial management which will, to a large extent, determine whether the player will win one of the four awards, namely, the “Individual Award” (the largest positive balance of good moral character cards); the “Family Award” (who has the largest amount of money by adding savings, remainder of investment, the total amount of family expenses times two, and cash-on-hand together); the “Donation Award” (the highest donation ratio); and the “Social Contribution Award” (long-term social benefits generated from personal donations). The game is designed to help students examine such elements in their lives.

Figure 1. The front page of the game “Live a meaningful life” (2015).

The time needed to finish the game is around 10 to 30 minutes depending on the number of rounds chosen by students. Throughout the game, students experience randomly different life circumstances, which are mostly uncontrollable. In this way, the game shows what real life can be and it is hoped that students can reflect on the meaning of life with the help of the instructors. They are also encouraged to learn to make personal financial decisions wisely in order to stay on the game and get awards in the end. Feedback is provided for players at the end of the game so that they can learn how to make better decisions and come up with other effective strategies to compete for the awards in the next round of the game.

Objectives

The game is designed to enhance students' reflection on personal values through discussing materialistic and non-materialistic values as well as the definition of a meaningful life. The objectives of the game are three-folded. First, on the cognitive aspect, students can understand their own view on financial management and have chances to practice it in the game. They can reflect on the values and meaning of life when making the decisions of how to allocate their salary in different categories such as family expenses and donation. Second, on the affective aspect, students can enhance their emotional competence in facing life issues beyond their control; and enhance their levels of empathetic competence and care for their community through experiencing the lives of different social classes. Finally, on the behavioral aspect, students can apply prudent financial management skills in the virtual reality. This will be a great learning experience for students, who may not have experience on how to manage their money on the whole in real life situations.

The purpose of the game is to help students understand that some things are beyond our control in life, such as one's origin and a financial tsunami. However, students could develop good moral character, learn prudent financial management skills, engage in careful decision-making processes, show more concerns toward society, and make donations, which are the crucial elements of a decent and meaningful life. This teaching material is designed for a teaching unit, MS 2.3 'A meaningful life'. The objectives are to help students to understand that good moral character is essential in leading a meaningful life; and sensible and smart financial management is important skills for managing life. The unit focuses on the construct of spirituality and self-efficacy.

Game Design

The physical design of the game is very similar to the board game 'Monopoly'. Players are allowed to choose their gender and the number of rounds at the beginning of the game. They will be assigned a social class with a fixed amount of monthly salaries randomly by the game. Lower class with \$10,000; middle-class with \$20,000; and upper class with \$30,000. The game will also generate three virtual players with different genders and social classes to join the game simultaneously. Players can see them at the lower right corner of the screen. At the beginning of the game, a fixed amount of rent will be automatically deducted from the salary. The player has to decide how to distribute his/her remaining salary to the following

items: personal consumption, savings, investments, family expenses, and donations. The remaining amount of cash-on-hand will be shown, and it is a crucial factor to determine if the player can carry on with the game. The player starts the game by throwing a dice and the icon of the player will move according to the number of steps shown on the dice. He/she has to decide how to use the salary every time when passing through the starting point on the board. The game is over when the amount of cash-on-hand is in deficit or the player has completed the number of rounds she/he chooses to play at the start of the game.

Throughout the game, players will have the opportunities to get good or bad moral character cards, which include kind-heartedness, diligence, contentment, health, family warmth, craving for knowledge, selfishness, laziness, greediness, criminal record, jealousy, arrogance, etc. Players will be given an award when the number of good moral character cards are more than the bad ones. In addition, there are four awards: The Individual Award will be given to the player who has the largest positive balance of good moral character cards; The Family Award to the one who has the largest amount of money by adding savings, remainder of investment, the total amount of family expenses times two, and cash-on-hand together; the Donation Award to the player who has the highest donation ratio; and lastly the Social Contribution Award to the one who has long-term social benefits generated from his/her personal donations.

Teaching and Learning Method

The teaching material is designed for a single user. It randomly assigns a social class to the player, who will virtually experience different life circumstances and unexpected changes that are mostly beyond their control such as accidents, change of economic environment, etc. On one hand, the players learn to use their monthly salaries through careful budgeting and planning. On the other hand, they are introduced to the significance of non-materialistic elements of life which include moral character, care for others, and contribute to society through donations. The game provides feedback to students on how to use money wisely and encourage them to search for the meaning of life at the same time.

Teaching and Learning Strategy

Instructors can introduce and demonstrate the game in class or during an assembly to arouse curiosity and interest in playing the game. Students can play the game in class or at home depending on the availability of time during lessons in school. Instructors are encouraged to focus on the reflection of the meaning of life, money and success, personal financial management, and the feedback provided at the end of the game with students. Social workers and counsellors can also use the game for group or individual counselling, especially for those who are weak in financial management or who over-emphasize materialistic values.

Besides, instructors can make good use of students' curiosity and interest in organising competitions in order to enhance the learning outcomes. In this way, students become more engaged and they can discuss as a group to win certain awards in the game. Since students will be assigned a different status at the beginning of the game, they have to employ different

strategies in personal financial management. Students might complain it is not fair that they are given the low social status most of the time while others are often lucky to have a high salary. Instructors can make use of some post-activities discussion on issues related to money and success, and the meaning of “being a winner” with students as they have gained some learning experiences through the game. Instructors should encourage students to try to get non-monetary awards such as the Individual, Donation, and Social Contribution Awards. This could provide food for thought to help students reflect on their own values and encourage a reflection on the meaning of life for students. Finally, instructors may remind students to use the print-screen function to save their personal financial management table for review purposes. In that way, they can review and analyze their practice of personal financial management, and initiate some discussion with their peers regarding strategies to win awards.

Tips for Instructors

Instructors need to explain to students about each item of expenditure and what are supposed to be included in the item. Most students lack the concept of running a family and do not understand much about budgeting within a household. For example, family expenses usually include all the bills like rent, water, electricity, internet fees, food, transportation, medical bills, etc. Activities such as donation to support a good cause and assist the less fortunate groups in the community is encouraged by giving two awards to players who regularly donate. If students have allocated an amount of donation, they will get a Card of Kind-heartedness automatically when they pick a surprise card that praises their willingness to help. On the contrary, overspending on shopping can cause 50% of one’s salary if one picks a surprise card. All these can be used for teaching points at the end of the game with students. They need to be careful about making purchases and instructors can bring up the possible “traps” of using credit cards and the high interest rate it incurs if one cannot repay the amount owed. There are plenty of areas instructors can discuss with the class such as the topic of “Spiritual Wealth” and its meaning. Positive behaviors will be rewarded like the value of hard work with a bonus of one-month salary when players land on the “work hard” square; and a card of arrogance is given when students land on the square of being overconfident. Instructors can encourage students to discuss the values and meaning of life using the materials provided in the game.

A Digital Game for the Project P.A.T.H.S.

To promote the holistic development of junior secondary school students in Hong Kong, the project titled “P.A.T.H.S. to Adulthood: A Jockey Club Youth Enhancement Scheme” was launched in the 2005/2006 school year. It is a collaboration with the research team involving scholars from five universities, the Social Welfare Department, and the Education Bureau (formerly the Education and Manpower Bureau). The project P.A.T.H.S. has been recognized as one of the evidence-based programs that apply prevention science [37] using 15 constructs identified as core components of positive youth development (PYD) [38].

Figure 2. The concept map of MS 1.1 “I Believe I Can”.

Teaching Points for MS 1.1

Instructors can lead students in the process of understanding and believing that we cannot develop many of the essential abilities with money, and we cannot rely only on money to deal with things properly in our daily lives such as our academic study and cultivation of friendship. Instead, we need to recognize one's self-efficacy in social, living habits, academic study, appearance, and financial management, and use one's capabilities to cope with one's day to day issues. When students have good performance, their confidence and self-efficacy will be enhanced. Thus, it will reinforce our coping capabilities when we are dealing with different issues in life.

Students are encouraged to believe in their talents, trusting that they are capable of doing many things well. Instructors can discuss with the class about the value of money, and list out things that money cannot buy, such as a warm family, sufficient sleep and good health. We can use considerate, reasonable and legal ways to obtain things that we deem important, but these are the things that cannot be purchased such as good friends and affection from others. Instructors can encourage students to discuss the value of money and other things with teachers, family and good friends to generate more constructive discussion on the issue.

Figure 3: The concept map of MS 1.2 "The Value of Life".

Teaching Points for MS 1.2

The unit targets at students who are at the age of exploring the meaning of life and their life goals. Some might start exploring different kinds of lifestyle which will lead to a different outcome. Should they pursue a more materialistic or non-materialistic life? Instructors can highlight the importance of participation in community activities such as volunteering in

community projects, shelters for homeless or senior centres. It helps enhance a sense of spiritual richness in students and as a result, it reduces their reliance on material goods for satisfaction, fulfilment or accomplishment. In fact, those feelings are short-lived and instructors can draw on personal experiences and real life examples to illustrate the point.

Students are encouraged to discuss what their life goals are with their teachers and classmates, and think about how they can achieve those goals. At the same time, instructors should help students to distinguish “needs” from “wants” in their daily lives, and encourage them to rethink the idea of “getting things because others have them”. Students can form into groups and debate about the reasons for and against the practice of purchasing something because “I should have things as others do”. This can stimulate students’ thinking of the logic behind the idea and come up with a plan to deal with the situation when they want to have something as others do. At the same time, instructors can discuss the value of life with students and remind them of the importance to have a balanced life. For example, students can try to reduce the consumption of materialistic goods such as snacks, clothes and games. Instructors can also encourage students to try practicing a good deed a day, serving voluntary in the community, and finding ways to enhance their spiritual richness. Having a walk in the park, going hiking and cycling with close friends and family or just helping a senior to carry his/her grocery will be a good start for students’ experience in this area.

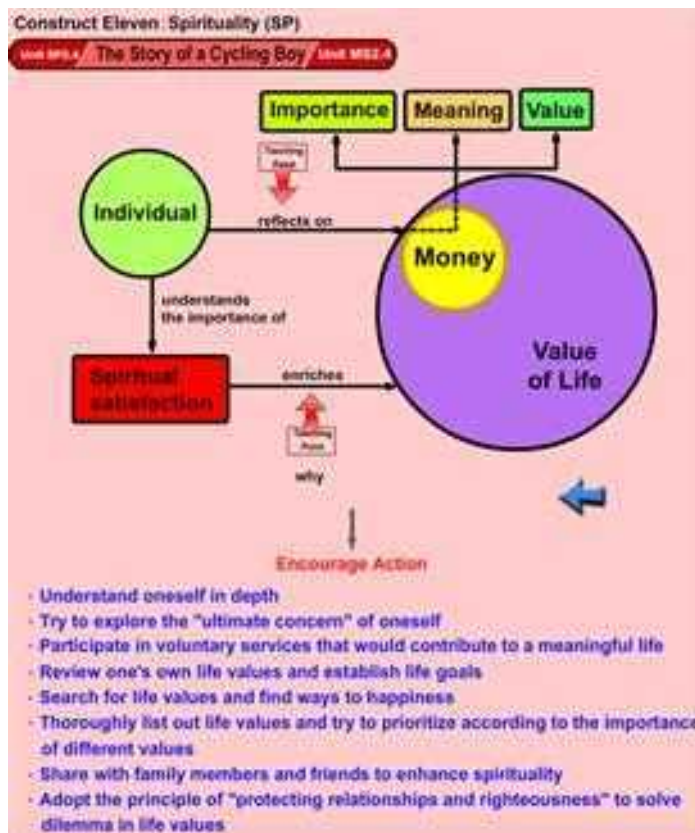

Figure 4. Concept map of MS 2.4 “The Story of a Cycling Boy”.

Teaching Points for MS 2.4

At the beginning of the story, a person who loved cycling developed a passion for cycling and set a goal of touring around the world. What is the meaning and value of life, and where does money stand in the equation? Instructors can guide students to discuss those questions and reflect on the meaning of money and other values in our lives. Students will be helped to think about the differences between “Material satisfaction” and “Spiritual satisfaction”. Instructors can ask students to share their experiences of both satisfaction and give them feedback accordingly. On the whole, the unit teaches how spiritual satisfaction enriches our lives and helps students understand the value of life which include a broad spectrum other than just money.

It is a golden opportunity for instructors to encourage certain actions in this teaching unit. We need to first understand ourselves in depth and try to explore what our “ultimate concern” is. Instructors can discuss with the class and review their own life values and establish life goals with them. This will facilitate students’ search for their life values and ways of happiness. Another exercise they can do is to list out students’ life values. Both instructors and students work together to prioritize according to the importance of different values. Students will be encouraged to participate in voluntary services that would contribute to a meaningful life; share their goals with family members and friends and spend more quality time with them to enhance spirituality. They will adopt the principle of “protecting relationships and righteousness” to solve dilemma in life issues.

Remarks

This game is designed to help students learn some important skills of managing finances, and understand there are circumstances in life where we have no control over. The happiness of life can be achieved by a lot of non-monetary values such as seeking and reaching one’s dreams, helping out in the community, or simply enjoying a quiet afternoon reading on a beach. Everyone has his or her own standard of happiness, students should learn to strike a balance between “Material Satisfaction” and “Spiritual Satisfaction” and should not rely too much on using material goods for happiness. The principles of “Helping others is the origin of happiness” and “Giving is more blessed than receiving” as well as the fact that “Maintaining fairness and promoting equality” can help students themselves and others happy.

User Feedback

The following comments were from a 15-year old girl attending an international school in Shanghai. Informed parental consent to play the game and publish her critical comments on the game was secured.

“The game resembles the popular board game Monopoly. Players use an electronic dice to move ahead but have free choices in gender, duration of the game of three, five, or seven rounds, and most importantly managing their monthly income. They will lose the game

whenever their accounts (money-on-hand) are in deficit. The game will end when players complete the number of rounds selected.

Positive Side

The game embodies a lot of elements in real life such as family, social organization, cultural practices, society, financial management, moral values, and value judgments.

First, the users have a free choice in distributing their salary in how much they are going to use in each aspect (personal consumption, savings, family expenses, and donation). The money remains will be the cash-on-hand. When the cash-on-hand is in deficit, the game ends. Each round, they have a choice to change their decision on how to distribute their monthly salary. This gives the users a good experience in managing their money. Users throw a dice to see how many steps they will move. Therefore, the players have minimal influence on where their chess will stand on. On some places, negative things will happen such as loss of money in investment, sickness, hospitalization and things that will use up money unexpectedly. These resemble the real-life situation that sometimes we need to use money in situations that we do not expect. In this case, students can learn to reserve a slightly higher amount of money for unexpected use. Most importantly, when players find that their money at a round is very close to zero, they will learn to prepare more money for cash-on-hand next time so that they will not lose easily. In this case, students can learn how to save money for unexpected things in real life situation and may not overspend.

Secondly, although the game focuses on how to manage money, it also promotes moral values. The players with the most money in hand can get an award but players who donate a great proportion of their salary, or who have the most good moral character cards, or who contribute the most to society can also get awards. This brings out the idea that not only is earning money important, other aspects such as family, personal warmth, moral values are also important elements in life.

Thirdly, this game is interesting as players may engage in some ups and downs in emotion when they step on rewarding squares and unfavorable squares.

Negative Side

First, as cash-on-hand is a crucial factor of the game, once a player's cash-on-hand is in deficit, he/she will lose the game. It is possible that after a few times the players played the game, they may put all or most of the money to cash-on-hand rather than putting them to personal consumption, savings, family expenses, and donation, in the hope of not losing the game rather than thinking of how to distribute the money in a real-life sense. Therefore, an experienced teacher and instructor may help players clarify their aims and targets when they play this game.

Secondly, it is possible that the game cannot promote the correct way of how to enhance familial relationship. Family award is given to the player who has the largest amount of money by adding savings, remainder of investment, the total amount of family expenses times two, and cash-on-hand together. Usually, players who were given the upper-class role will

spend more money (not in ratio) in family expenses than the middle-class and the lower-class because they have more money. There are a lot of reasons and ways to achieve a harmonious family relationship. Money is only one of the important factors. Although the aim of the game is not to bring out the idea that money is the most important factor in maintaining familial relationship, the game somehow works in this sense. It is possible that students may neglect other crucial factors which could promote good familial relationship such as time spent with family, tolerance, and understanding.

Thirdly, it is better if some small games that could promote correct values judgment can be added to some squares on the board. If players stop on some certain squares, they will be given some positive or negative moral value cards (e.g. greedy, jealous, hard-working, and healthy). Students may not have a deep impression of those values. It is possible to add some small games or some short questions about the corresponding values on those squares. So if students answered them correctly, they can avoid getting bad cards and get good cards. In this case, students may find it more fun as they have to work or discuss to get good cards and avoid getting bad cards, instead of getting them without doing anything. In addition, the game designer can also instill correct value judgments and moral values to students in those questions.

To conclude, the game is interesting enough to arouse students' motivation to play it more than one time. And, the frame of the game was nicely structured. However, some small changes may be needed to improve the game."

The following comments were from a Chinese female young adult (21 years old), a university student from Hong Kong.

Pictures

There are a clear starting page and a clean and clear image of male and female characters for players to choose. The colorful checkerboard is eye-catching and therefore, it is able to arouse my interest in playing the game. The artworks match the description of different life situations with clear instructions.

Game Design

The rules were clearly stated. The important rules that describe different points counting system are highlighted in different colors. However, it may be better to specify the use of remaining cash in the game. The use of dice was good in the game as the randomness of the dice resembles the unpredictability of life. The quote in the end can let me reflect on the meaning of life and daily life decisions.

Content

There are four awards in the game which are individual, family, donation and social contribution. This helps me know that there are different values in life. It is good that the cards are written with different kinds of attitudes and feelings. So it can concretize some abstract description. The reasons given when I get a particular card (attitudes and characteristics) can let me know what specific behaviors are classified as certain characteristics. The game also includes different kinds of situation that adolescents and young adults may encounter when they start work. Lastly, the personal financial management table

helps me think about how I would spend my money meaningfully. The financial management table can reflect a player's spending pattern and his/her value towards money and success.

Effect

Different situations can impress me and help me think deeper (e.g. work hard so that I can get a card of diligence and bonus of one-month salary; you will get what you deserve; once you work hard, how much effort you make, how much you get)."

DISCUSSION

Our findings suggest potential effectiveness of the electronic learning material. From the feedbacks of the users, the design of the learning material is easy to understand and interesting as it is similar to a popular board game named Monopoly. Most importantly, users agreed that the game helps students acquire money management skills and understand moral values, which is the primary goal of designing the game. The feedbacks are consistent with a previous study that a well-designed and clear instructions digital games is beneficial to adolescents in terms of learning financial literacy, supporting the game-based learning phenomenon in schools [32]. The feedbacks have provided some insights to a well-designed DPYD game for young people. For instance, colorful pictures and gorgeous animation attract young people to play the game, increasing their motivation to learn. Moreover, the game has clear learning objectives which are extremely crucial.

Secondly, the effect of teachers' involvement in the process of learning is not ascertained as this is not the focus in this study. However, from the feedbacks of the users, teachers or instructors play an important role in clarifying the learning objectives of the game and indicating a positive effect to enhance the effectiveness of the game. Besides, as pointed out by Kim, Lee [39], teacher support significantly influences youth people who display maladaptive behaviors. Franklin, Kim [40] showcased the effectiveness of school-based psychological intervention delivered by teachers. Teachers not only assist adolescents to learn but also play a therapeutic role which requires further studies to confirm their influence. In addition to their role, teachers can also act as a facilitator to assist in the discussion amongst adolescents on the topic, and getting feedbacks from their fellows. If players receive feedbacks regularly during their learning process, the game is more than just entertainment but a deep learning process for the players [30]. To tackle materialism in youth, it is no doubt that educators should be involved.

Thirdly, a previous study has found that Chinese adolescents from different age groups exhibit different levels of materialism, which reveals materialism increases with age [41]. Impulsive buying behaviors increase with age and female shows more impulsive buying compared to male [42]. In response to the gender and age differences, game designers might have to provide a guideline to teachers or instructors to ensure the learning materials are applicable in adolescents with all age range.

Finally, adjustments on the content of the learning materials are suggested. One user shows concerns that the game might be over-emphasizing on money to maintain family relationship while money is just one of the factors that can promote family harmony. Also,

some mini games can be added into the game in order to help players to make correct moral judgements and understand correct moral values.

Limitations

First of all, the feedbacks in this study do not represent the effectiveness of the learning material. The feedbacks are the fundamental ground for further studies. They are purely opinions of the users that cannot be generalized to a greater population. This is because qualitative method is not designed to test whether the result is statistically significant or due to chance [43]. In fact, the utilization of game-based learning on financial literacy is a relatively new concept that almost no research has been done in Hong Kong. With limited knowledge in this area, it is difficult to make an in-depth conclusion on the effectiveness of the game. Further research on this area is recommended, especially testing the effectiveness of game-based learning on money management using quantitative method with rigorous methodology and validated measurements. In addition, the data in this study is collected only from two individuals. Thus the result in this study should be interpreted with caution.

Apart from that, the game does not cover other protective factors of materialism such as promotion of gratitude [28], social comparison with friends and media influence [12]. These factors should not be ignored in the interpretation of the effectiveness of the game. Financial education is one of the possible solutions to tackle the problem of materialism in youth people.

Finally, it is also worth mentioning that the game design itself is limited to money literacy in young people to reflect on materialistic and non-materialistic values. Other factors that contribute to materialism such as parental influence cannot be addressed. Based on the model by Chan and Prendergast [12], social learning from family members on materialistic values contributes to the development of materialism. For those who are strongly influenced by their parents' materialistic value, this learning materialism might not be as effective. Special training in teaching skills is needed to help this group of young people to deal with their conflicting values [35].

Testing the Effectiveness

This study did not obtain any quantitative data on the level of materialism of the students. Future studies can conduct a thorough quantitative research to test the effectiveness of the game with regard to minimizing materialism among adolescents. Studies have been done in Hong Kong or with Chinese population to explore materialism in adolescents with translated measurements with validation [12, 17, 18]. The Chinese Adolescent Materialism Scale (CAMS) is also ideal to be administrated to test young people's level of materialism as it measures materialistic beliefs through several aspects related to materialism which include morality, spirituality, egocentrism and empathy [8]. To test the effectiveness of the game, a pre-test and post-test design is recommended. The study could first examine the level of materialism using Richins and Dawson [44] Material Values Scale before introducing the learning material. After students have completed the game, the same set of questionnaires

could be done by the same group of students in order to find out if there are changes in their level of materialism by comparing the scores before and after introducing the learning materials. Hieftje, Edelman [45] believed successful electronic media interventions should promote behavior change. Future studies could also measure behavior changes of the students who have played the game. From that, the effectiveness of the game could be concluded.

Apart from testing the effectiveness of the game, it is also worth investigating the contribution of teacher's participation. From the feedbacks, teacher seems to play an important role in students' learning process. Therefore, a cross-sectional study comparing the level of materialism between the group of students with teacher's guidance and the group of students without could provide an insight on the effective implementation of the learning materials.

CONCLUSION

To conclude, the learning materials can educate young people on money literacy. Some adjustments are needed on the game for students to understand the concepts of financial management. Further investigation on the effectiveness of the materials through quantitative method is needed to reach an accurate conclusion on the effectiveness of the game. Overall speaking, the game is a form of "Edutainment" for the promotion of positive youth development among adolescents.

ACKNOWLEDGMENTS

The design and production of the 7 digital games introduced in this special issue, the preparation of this work, and the Project P.A.T.H.S. were financially supported by *The Hong Kong Jockey Club Charities Trust*. Readers may request free copies for non-commercial purposes of these games by contacting Dr. TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This chapter is based with permission on a paper adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

ABSTRACT

Research supports that evidence-based positive youth development (PYD) programs assist adolescents in dealing with developmental problems. One major adolescent issue is relationship, particularly friendship and courtship. Deterioration in bonding with parents and inadequate support from psycho-socially mature adults are commonly found in urban cities around the world. High divorce rate is an indicator. Many adolescents grow up in families with insecurity, lacking proper social and emotional support. The lack of appropriate role models and parental guidance are risk factors for adolescents having troubles in their peer and romantic relationships (PRR). A digital positive youth development (DPYD) game with an aim to enhance the core competencies of adolescents in building and maintaining PRR, which incorporates literature as learning materials, has been developed and made available for free educational use. The game employs both Chinese and Western literature in a bilingual context to provide examples to engross the players' attention and facilitate their understanding of the concepts through stories and practice tasks. Not only does it help promote proper attitude and enhance necessary knowledge and skills, but it also helps foster players' self-awareness and self-reflection through literary references. This paper contributes to cross-disciplinary methodology in using literature in the design and development of DPYD games, as well as providing a

* Corresponding Author's Email: sarahlee@hkbu.edu.hk

significant reflection on the nature and function of literature and its importance in promoting PYD among adolescents.

INTRODUCTION

In Hong Kong, only three out of one hundred students took the subject Chinese literature in the post-secondary examination in 2018 [1]. Moreover, in 2017 only 33.6% of secondary schools offered the subject, which is a 23% decrease compared with that of 43.7% in 2012 [2]. Apart from students' heavy study load, another reason is students' perception of literature as difficult and dull. Moreover, literature is regarded as an impractical subject which does not guarantee students a good career prospect in a business and technology-oriented society. Nevertheless, literature is vital to the cultivation of an individual's morality and virtue and the understanding of the root of culture and history. With financial support, a digital positive youth development (DPYD) game to promote proper attitude and enhance knowledge and skills about peer and romantic relationships (PRR) is developed. The game is also designed to enhance exposure to traditional Chinese values and classics from Chinese and Western literature. Through appreciating the beauty of literature, students' perception towards literature might gradually change and they might find literature useful and intriguing, helping them build the habit of reading literature.

A JOURNEY TO SOMEWHERE, TO SOMEONE

The game, 'A journey to somewhere, to someone', simulates taking a journey with friends who might become intimate friends, exploring different landscapes and examining the meanings and principles behind. It aims to help players learn core elements of social interaction with peers, crucial qualities of friendship, and important knowledge and skills for engaging in PRR. The Growth Road Railway has seven stations which include Pingjin Lake Station, Pingshui Station, Hundred-year-old Trees Station, Friendship Mountain Station, Hazy Moon Station, Watchful Station, and the terminal station, Love Road Station. Each station has different contents and game elements through which players learn PYD constructs and related knowledge and skills.

Pingjin Lake Station aims to deepen students' self-understanding; Pingshui Station helps one understand the opposite gender and reduce gender stereotypes and biases; Hundred-year-old Trees Station serves as an examination of friendship; Friendship Mountain Station helps differentiate desirable from undesirable friends; Hazy Moon Station aims to deepen learners' understanding of the differences between like and love; Watchful Station enables the learning of the fourteen crucial elements of building, maintaining, and enhancing PRR; and Love Road Station introduces players to the seven stages of romantic relationship. The design helps students learn step by step. Each part is equally important, and the topics are interrelated. Therefore, students are encouraged to play the game repeatedly and thoroughly in order to achieve more in-depth learning outcomes.

The game provides short stories from Chinese and Western cultures. It also uses Chinese poetry, essays, and literary knowledge. To engage players, short quizzes, psychological tests with feedback, and small games are included. Players will be attracted by the journey to reach the final destination, Love Road Station, which stimulates engagement and motivates them to continue playing the game.

With the examination of the values behind human affairs and self-reflection, students are given opportunities to improve their self-awareness, learn to get along with good friends, change their behaviors, maintain and enhance friendship, and finally obtain necessary knowledge, attitude and skills required at different stages of romantic relationship.

LITERATURE REVIEW

Bonding is defined as “the emotional attachment and commitment an individual makes to social relationships with parents, caregivers, siblings, peers, schoolmates, teachers, romantic partners, and other members of the community throughout the whole life circle” [3, p. 1]. This paper focuses on students’ bonding with friends. Peers play an important role in providing physical and mental support, intimacy and guidance, which are the key foundation of adolescents’ self-worth and self-esteem [4]. Companionship of friends is found to help one cope with alienation and adversities that favors the construction of a sense of belonging and higher level of social acceptance, enabling a smooth integration into the community and society [4]. Positive bonding with peers also correlates with students’ psychological health and whole-person development. On the contrary, negative peer pressure could result in the imitation of friends’ aversive behaviors, such as smoking or drug abuse. Hence, the game aims to teach students to distinguish between helpful and harmful friends and ways to build and maintain friendship in order to enlarge their social circle and have a fruitful social life.

Literature in Game-Based Learning

Literature is not used in the first two stations as the game adopts a step-by-step approach to avoid teaching difficult concepts at the beginning, which might hinder students’ incentives to continue playing the game. According to Nor and Wong’s [5] report on the design of history digital game-based learning software, it is recommended that “design must be immersive, motivating, engaging and playability high” (p. 12). Literature is often perceived by students as difficult and boring. Hence, the incorporation of small games, short quizzes, and psychological tests with feedback would be effective in the formation of new concepts and the development of cognitive thinking and skills [6]. This would alter students’ prejudice against literature and could strengthen their interest and motivation to read more Chinese and Western classical literature. Conceivably, students could develop a long-term reading habit, favoring the enrichment of knowledge and the cultivation of good virtues.

STATION 1: PINGJIN LAKE STATION

Students can enhance self-understanding of their personality traits, including strengths and weaknesses. Through determining the described features, such as lively, stupid, fair, and proud, on the scale of ‘completely different from me’ to ‘exactly like me’, students could obtain feedback on their self-image. This not only increases learners’ engagement but also fulfills the objective of self-understanding, enabling them to reflect on their bad habits and encourage them to acquire more positive traits. Moreover, the game is tailor-made for students of various personalities. If they demonstrate a very positive self-image, they could directly head to the third or fourth station. For those who have room for improvement, they are asked either to select some of the personality traits they want to improve or to choose positive qualities they desire to have. Self-understanding is fundamental for building and maintaining PRR, paving their way to latter stations of seven levels of friendship and fourteen essential qualities [7].

STATION 2: PINGSHUI STATION

One’s first impression to an unacquainted person is largely determined by their appearance. Gender stereotype and prejudice shaped by social norms might obstruct one’s relationship with others and even hinder human interaction. The game offers a test which checks players’ attitude towards males and females. Despite the fact that no absolute right or wrong answers are given in the game, students would be asked to rethink whether common expectation of both gender is reasonable. Girls are often perceived as narrow-minded and temperamental, while boys should be brave, independent, resolute, rational and active. The game would then remind players that these are groundless gender stereotypes and that girls and boys can have various traits. Youngsters after completing the tests could have a conceptual change, freeing them from traditional/subjective bias and encouraging them to strive for gender equality through actions. Positive identity and social competence are thus enhanced as they learn to accept differences and respect diversity. For students who are not fully familiar with the concept or could have improvement, they are recommended to read a short passage and complete a yes or no question, ensuring an awareness of gender stereotype before moving to the next station.

STATION 3: CENTURY-OLD TREES STATION

Students have to reflect on whether they are a good friend to others by selecting the most suitable answers to the questions relating to their friends and they would be given feedback afterward. Based on an individual’s response, if one is confirmed as a helpful friend and a wise companion of others, one is qualified to speed up the pace and directly proceed to the fourth peak ‘Acquaintance Peak’ of Friendship Mountain Station. This reveals the customized-nature of the game with corresponding adjustment according to the students’ character and ability.

First, learners start by understanding the cultural differences of friendship in Chinese and Western cultures. There is a saying in *The Analects of Confucius – Wei Zheng* that goes, “Show your kindness towards your friends as they are like your brothers” [8]. In traditional Chinese society, real friends can even swear to live or die together, implying the intimacy between friends is only second to that of filial relationships. On the contrary, western culture emphasizes individualism, which implies that people sharing similar thoughts would gather together but they will go separate ways if they hold different views. To conclude, Asians are relatively more “interdependent and relationship-oriented” compared with westerners [9, p. 1476]. Hence, Westerners might have difficulties understanding the Chinese ways of hospitality. Students would learn to respect one another’s diversity and the cultural differences between east and west, cultivating the spirit of embracing those who hold different opinions. This lays a solid foundation for the construction of one’s social competence and bonding with others.

Second, students have to develop the ability to distinguish between beneficial and harmful friends. According to *The Analects of Confucius – Ji Shi*, there are three types of desirable and undesirable friends respectively. One should make friends with those who are upstanding, honest and knowledgeable, and stay away from people who are obsequious, good at tempting and using dishonest rhetoric. Adolescents are hugely influenced by their peers which could lead to “peer contagion”, referring to the “influence among peers that results in the spread of shared behaviors” [10, p. 249]. The quote in *The Analects of Confucius – Wei Zheng*, “I do not see how a man who is untrustworthy in words can be acceptable” introduces the two moral values, integrity and uprightness, that are indispensable in helping students get along with others in society [11]. Learners will gradually find literature useful and applicable even in modern society.

Third, loyalty and faithfulness are necessary in the maintenance of friendship. To cultivate the mentioned virtues, one could learn from Zeng Zi, who examined himself on three things every day. “In what I have undertaken on others’ behalf, have I failed to do my best? In my dealings with my friends, have I failed to be trustworthy in what I say? Have I failed to practice repeatedly what has been passed onto me?” [12] Constant reflection on oneself would remind one to be honest and loyal to one’s responsibilities. Moreover, youngsters should not look down on anybody as everyone has his/her own strengths. They are advised to hold a humble attitude to learn from others’ merits and rectify their shortcomings as Confucius instructed in *The Analects of Confucius – Wei Xue*, “Do not make friends with anyone who is not as good as you. When you make a mistake, do not be afraid of mending your ways” [12, p. 34]. Undoubtedly, literature serves as a good model for one to follow the skills of pursuing good virtue and self-reflection.

Literature can guide one to look for bosom friends with whom the friendship would last long. According to *The Analects of Confucius – Yan Yuan*, “Use writings and knowledge to meet one’s friends, and through ones’ friends to develop ones’ benevolence. Form a literary circle and make friendship as a help to right conduct” [12, p. 509]. Through the reading of orthodox literature, one’s cognitive knowledge is enriched and one is able to better express one’s opinion. This fosters the communication and exchange of thoughts with like-minded people, which could enhance one’s temperament and benevolence [12]. Bosom friends are like mirrors, who would kindly point out all demerits of one another for the sake of helping them. Selfishness and self-centeredness are replaced by mutual trust. With the support of one another, both would together proceed on a correct path to success. Realizing the importance

and benefits of reading literature, students would be motivated to study more Chinese classics.

Quotes from Chinese classics are integrated into this station which acts as a warm-up activity for students to get prepared for literary stories in Hazy Moon Station. Concepts introduced in this station will further be elaborated in the next station and applied in actual practice, which is the seven levels of friendship that provide guidance for students to build and maintain intimate relationships with peers.

STATION 4: FRIENDSHIP MOUNTAIN STATION

Station 4 lays out seven levels of friendship and outlines a stepwise and systematic guidance for students to build and maintain friendships.

Massive Crowd Peak

Students could learn to identify the characteristics of their personalities and reflect on their way of getting along with others, which favors the improvement of the modes of communication with others. The test of identifying the best descriptions that match oneself provides a personalized learning approach which could cater for students of different personalities and backgrounds, enabling them to understand their role in the relationship, attitude when treating people, and way of dealing with matters based on their responses. Suggestions are also given for one to learn to get along with people of different personalities. For example, one is advised to respect others' opinions and reach a consensus through communication with people who are dominant and proactive. This lays the foundation of building friendships as researchers found that the most explicit strategy in maintaining friendships as well as romantic and familial relationships was "direct discussions and listening to one another" in a large sample of undergraduates [13, p. 207]. Acknowledging one's shortcomings and acquiring communication skills would improve their social and behavioral competencies of maintaining a relationship.

Followers Peak

Students could get exposed to the four levels of friendship in Chinese literature, ascending from 'friends of wine and meat', 'friends with common interests', 'friends with righteousness' to 'sworn friends for life and death'. To elevate one's friendship and become confidant of one another, sincerity is the most crucial principle. Confucius and Zuo-qiu Ming once mentioned in *The Analects of Confucius - Gongye Chang* that one should directly speak one's thoughts to one another if resentment and problems arose, instead of pretending nothing has happened and keep getting along with them. As a true friend, one has the responsibility to advise one another on the basis of equal status [14]. On the other hand, Western culture recognized the importance of sincerity in friendship as evidenced in the saying, 'When getting along with friends, your personality should be exposed thoroughly to one another' [14].

Literature contributes to the facilitation of implicitly maintaining friendship by highlighting the significance of self-disclosure and providing mental support [13]. Understanding the wisdom of maintaining friendship through reading classical literature, students' cognitive knowledge would be further enriched, and they would be reminded to treat friends with a sincere heart.

Acquaintance Peak

Through *The Analects of Confucius*, students could understand and identify the determinants for desirable and undesirable friends. Students are recommended to make friends with those who have a firm stance, are fair and honest, are willing to assist others to go forward and be responsible, and dare to admonish their friends directly. They are also reminded to stay away from those who are ingratiating in action and place too much importance on pleasant appearance and plausible speeches [14]. Friendship quality is featured as "the nature of friendship interactions" which would be influenced by the factors of "pro-social behavior, loyalty and intimacy, and few conflicts" [15, p. 517]. Having quality friendships has been proven to have a positive association with one's psychological well-being [4, 15], which contributes to adolescents' behavioral regulation and cognitive and emotional competences [15].

Owing to the fact that helpful friends are good listeners and advisers, providing "guidance, reassurance, acceptance, sympathetic listening, encouragement, feedback and a sense of belonging" [4, p. 666], they are key socializing agent of youngsters to adjust their behaviors and communication skills. Social support provided by friends could boost the feelings of self-worth and self-esteem of youngsters, enhancing their psychological health development and bonding with peers [3]. In contrast, social learning theory and primary socialization theory are used by Kobus [16] to explain that adolescents might go astray if they imitate deviant behaviors from peers such as smoking and doping [3]. Knowing the importance of making worthy friends, adolescents could make right decisions when making new friends, maintaining a close relationship with those who are credible and knowledgeable, and distancing from harmful friends.

Knowing Peak

When getting along with friends who have different characteristics, one has to adjust his/her attitude based on the situation or characters of the other party in order to avoid clashes or confrontations. One should consider raising their demands when working with those who are lazy, indifferent or disrespectful. One is advised to make requests when facing those who are sensitive, short-tempered or experienced but lack enthusiasm. Remembering the suggestions, students would be able to make the correct judgement and decisions when encountering similar situations. This strengthens one's ability to handle matters and cope with adversity, promoting PYD [3]. Besides, provision of material and mental support to friends are essential in maintaining an intimate relationship [13], for instance, lending a helping hand to them when they have to complete a particularly difficult or annoying task. The knowledge

acquired paves the way for students to proceed to the next station, enabling them to have a more in-depth understanding of the literature and the qualities, which are assistance, devotion and reciprocity.

Good Friends Peak

Establishing and maintaining mutually trusting relationships with friends require time and joint effort from both parties. This station serves as a warm-up activity for students to have a glimpse of the qualities one should possess to enhance an intimate relationship with others, which correlates to the fourteen elements in Watchful Station. Students are reminded to respect friends' freedom of expression, accept unconditionally and trust everything about them, and keep the conversation confidential. Self-disclosure, which is the revelation of private and sensitive personal information to others, would be effective to build trust and foster intimacy in a relationship as it indicates commitment and the willingness to expose one's weakness [9]. One would be emotionally involved with peers' disclosure, implying that they are starting to be aware of and understand others' emotions [17]. The ability to express empathy demonstrates their awareness of catering to the needs of others and putting themselves into others' shoes, favoring the development of "interpersonal priming, self-awareness, mental flexibility, and emotional regulation" [18, p. 248]. Having a basic understanding of the above important qualities helps youngsters build a solid foundation, ensuring a smooth transition to Watchful Station, in which large amounts of Chinese and Western literature are included. They could thus better immerse in classics and have an in-depth knowledge of the fourteen core components, and integrate theory into overt behaviors. As Tillman and Prazak [19] proposed, "developmentally important skills include those related to communication, conflict resolution, developing and maintaining trust and intimacy, which in turn facilitate friendships that may serve as basic building blocks for adult relationships of an intimate nature" (p. 158). Students are encouraged to practice skills that establish or promote trust among classmates, which strengthen their bonding with peers.

Fraternity Peak

It is essential to form literary circle as literature not only cultivates one's well-being and virtue, but also helps one make friends with those who share similar hobbies and visions. *The Analects of Confucius* - Yan Yuan states, "Gentlemen gather together with friends to talk about literature and art. They develop benevolence through the support of friends" [14]. Through the reading of Chinese and Western literature, students could savor the words and appreciate the content, through which their vision would be broadened by exploring ancient people's social lives and emotions [20]. The reflection on the connotation and the value of life fosters the gradual formation of their own ideals and codes of conduct, helping them become a person with great virtue and a strong sense of social responsibility [20]. Moreover, one's passion in reading literature and pursuing knowledge would draw us to those who share similar aspirations. Hence, talking about literature and art with friends promotes a common language and genuine exchanges of opinion. Echoing with the saying in *The Analects of*

Confucius - Zi Lu, “Friends should encourage one another and exchange views with one another.” This suggests the significance of literature in assisting one to look for long-lasting friendships where peers could always support one another and enable one to learn from their strengths, striving together on the rightful path in life [14].

Confidant Peak

The supreme level of friendship is to be friends until or even after death. One of the examples in Chinese classics is if a friend of Confucius passed away and nobody undertook his funeral, Confucius would take care of it [14]. This implies that friendship persists no matter in life or death. Even after the death of one’s closest friend, one should still treat them benevolently. Ancient people’s emphasis on confidant would move youngsters’ heart, making them rethink whether they are willing to go through trials and tribulations with one another and determine whom one’s real friends are. The real-life stories of Confucius may enhance students’ social and moral competencies. For example, Confucius’ student Zi Lu always shared his carriage, horses and clothes with his friends, without caring about the objects’ wear and tear [14]. This sets a perfect model to educate youngsters that the amiable relationship between friends outweighs the value of possessions. Besides urging adolescents to reject materialism, classical literature reminds youngsters of traditional Chinese values where group intimacy and altruism are emphasized. As Confucius once mentioned, “the teaching of respect to one’s elder brothers is a preparation for serving all the elders of the country” [21, p. 69]. By reinforcing a sense of social altruism, people are reminded to be generous not only to family members, friends, and lovers, but also to less closely related individuals in society [22]. When understanding that sharing is more blessed than receiving, one would be eager to help those in need, which helps enhance one’s moral and social competencies.

STATION 5: HAZY MOON STATION

Social, moral and emotional competencies could be enhanced from classical literature and poetry, for instance, the Chinese ancient classic *Book of Poetry*. Confucius proclaimed, “the verses of *Book of Poetry* can be concluded in a single phrase - Don’t think in an evil way”, which is to guide people on the right path through the provision of correct knowledge on morality and romantic relationship [23]. In Station 5, six poems are provided to students as a warm-up activity to have a taste of the three core components of love, namely passion, commitment, and intimacy.

Firstly, commitment refers to “a short-term decision to love someone and a long-term commitment to a loving relationship” [24, p. 330]. This could be manifested in two poems: *Guan-guan* (‘The Osprey’) edited by Confucius and *Sheng Zha Zi* by Ouyang Xiu. *Guan-guan* expresses the yearning and pursuit of pure love by ordinary ancient people and reflects the healthy and sincere thoughts/feelings of the youth [23]. While students are free to fall in love with another person, just like the author in the poem, they are responsible to commit in the relationship when encountering true love and see marriage as the ultimate form of love [25].

Sheng Zha Zi describes the feelings of breakup and separation of a couple, and one would be moved by the sorrow and commitment of the author. “Tears soaked the sleeves of my spring gown” manifests the difficulty to part and how deeply the man once loved his partner [26].

Secondly, passion is defined as the “internal forces that lead to romance, physical attraction, and sexual satisfaction” [24, p. 330]. One could experience the passion of ancient people in the poem *Flower? Not Flower* written by Bai Juyi which expresses the author’s longing for love. Scholars generally agreed that the background of the poem is the poet’s affair with a lady, allegedly a prostitute. Just as short-lived as the flower and the haze in the poem, his love may be intense, but lasting no longer than flowers and haze [27].

Another poem is *Butterflies Love Flowers* by Su Shi, expressing delicate feelings of vacancy and loss. A passer-by was attracted to stay and listen for a while by the sounds of swings and laughter from a fair lady within the garden wall, but after her laughter faded away, the passer-by could only take a deep sigh for his ‘sensation being disturbed by the reality’ [26]. In spite of encountering failure in love, teenagers are encouraged to continue to seek true love.

Thirdly, the two poems by Liu Yuxi in *Song of Bamboo* convey the feeling of intimacy in love which includes “such qualities as experienced happiness with the loved one, mutual understanding, intimate communication, and emotional support” [24, p. 330]. The first poem demonstrates intimacy through dating activities. Referring to nature in the background, the persona portrays her feelings towards entering a romantic relationship [28].

The other poem portrays the worries of a woman that the love of her lover would be fleeting like peach blossoms. Then, an infinite gloominess came upon her like endless river currents [26]. It is common for one to feel anxious and nervous in a love relationship, for fear of not being loved by their partner. However, one should be honest and try to communicate with their partner in order to eliminate the uneasiness to maintain intimacy [29].

Distinguishing between Love and Like

The exposure to literature and poems could enrich youngsters’ understanding of love and help them develop the ability to distinguish between ‘love’ and ‘like’. Different from ‘like’ which could be merely out of physical attraction or similarity of personality, ‘love’ consists of three core components: passion, intimacy, and commitment, resulting in the desire to possess and the exclusion of others [24]. The story of Su Shi is a good example to determine whether one has found their true love. Su Shi, one of the greatest writers in Chinese literature, expresses his deep feeling of grief and remembrance towards his dead wife, Wang Fu, through the poem *Jiang Cheng Zi*, revealing the highest level of love: love would never perish due to death [26]. In the ten years after his wife’s death, Su Shi tried very hard to forget her, but she was forever in his mind. His deep sorrow and affection touch the hearts of many readers and invite youngsters to reflect on what is meant by true love. A precious lesson is taught to adolescents, reminding them not only to be the only one for each other, but also to love one’s partner even after their death. Absorbing new knowledge of love, students would think twice before starting a romantic relationship or devote their time and effort only after having a deep understanding of their partner, which resonates with the “cognitive processes”

that enables them to use a reasoning process of deciding what to believe and critically examine one's own thinking in order to make appropriate judgement and action [30].

STATION 6: WATCHFUL STATION

Maintaining a stable and harmonious relationship with both same and opposite-gender friends and furthermore, partners, requires both parties' contribution and sacrifice of their time and effort. One would be motivated to improve his/her personality, cultivate a sense of responsibility and even the selfless sacrificing spirit. To achieve the above goal, one has to possess fourteen essential elements: understanding, equality, pleasure, acceptance, devotion, assistance, trust, respect, loyalty, self-esteem, reciprocity, defense, maintenance, and confiding.

Mediation Sea (Theme: Understanding)

The ideal personality traits in Chinese and Western cultures are listed respectively, which share great similarities, for instance, advocating the complete morality of benevolence, righteousness and wisdom, and the maintenance of an honest and sincere attitude towards others [31]. Understanding the qualities could help one set up goals and motivate one to pursue them in life.

Balance Village (Theme: Equality)

The need to go on a business trip separated Qin Jia from his wife Xu Shu, so they could only express sorrow, remembrance and deep love through letters [32]. This Chinese love story demonstrates the ideal of mutual love and respect between spouses, where one should always be courteous to their partner and be devoted to them.

Comfort Forest (Theme: Pleasure)

Yu Boya became bosom friend with Zhong Ziqi as they appreciate each other's musical attainment and find connection in the pleasure of music. This is similar to the western story of Robert and Clara Schumann, who fell in love due to their shared passion in music. Even after Robert's death, Clara continued to promote his work as they were not merely partners, but also each other's bosom friends, who shared pleasure in their musical journeys. Students would learn to reinforce friendships through spiritual pleasure.

Patience Mountain (Theme: Acceptance)

The Chinese short story of Lin Xiangru and Lian Po shows two high-ranking officials willing to put aside rancor and forgive each other. On the other hand, the Western short story uses a bag as a metaphor of hatred. The more attention you pay to it, the more the hatred expands [33]. Both ask players to be mindful of hatred and be forgiving.

Dedication Spring (Theme: Devotion)

The friendship of Guan Zhong and Bao Shuya and the story of Samuel Walton who founded Wal-Mart Stores teach students a lesson about devotion. The former manifests the importance of trust and willingness to sacrifice and devote oneself to another without demanding return; while the latter demonstrates Walton's great sense of sincerity, responsibility, and devotion [33]. Devotion decides a person's mental and moral nobility, which not only helps improve a person's well-being, but also one's relationships with others.

Thousand-Hand Cliff (Theme: Assistance)

Assistance is not just about material or emotional support, but also spiritual help. Guan Ning ended his friendship with Hua Xin due to his friend's inattentive attitude, but his act was to assist Hua Xin to reflect on the value judgments behind his behaviors, hoping that he would make improvements. Former US President Barack Obama's considerate, humble and straightforward personality won the support of his wife, the public and even his opponents [33]. A spiritual level of help with deep spiritual connection enables one to extend the meaning of life and improve one's shortcomings.

Heart-to-Heart Lake (Theme: Trust)

The two Chinese short stories, the friendship of Fan Shi and Zhang Shao, and the trustworthiness of Jin Wengong, emphasize trust and the importance of keeping one's promise, from a promise for a meeting to a promise to citizens by a high-ranking official. Similarly, in a western story, Damon was willing to trust his friend Pythias in face of an imminent death penalty. Trust is the basic condition of getting along with friends, and keeping one's promises is the first step for building trust.

Respect Lake (Theme: Respect)

Mencius mentioned one should "look humble outside and be respectful inside", implying that respect to parents, friends, and lovers has to come from the heart [34]. Saying and teachings from Confucius reveal the emphasis of filial piety and respect in traditional Chinese society, which are the basic qualities of one's well-being.

Fidelity Rock (Theme: Loyalty)

Loyalty is of utmost importance in a romantic relationship. Take the modern story in the game as an example, one should not hang out alone with a friend of the opposite gender simply because one's boy/girlfriend is not available. A romantic relationship is extremely fragile and has strong exclusivity where the intervention of other parties is not allowed [34].

Awakening Rock (Theme: Self-Esteem)

One would sometimes be depressed or feel helpless when facing difficult tasks and adversities in life, but one must not lose the belief of self-respect [12]. The two Chinese short stories describe two persons having great ambition and open-minded confidence respectively even after being relegated. This motivates students to have confidence and determination for making improvements, which would favor their building of positive self-esteem.

Symbiotic Wood (Theme: Reciprocity)

Confucius advocated a person's positive character is the most important consideration in choosing friends, instead of their social status or wealth [14]. Relationship built on mutual development, for example, the exchange of opinions and thoughts, is more long lasting than that of materialistic interests [14].

Jintang Brook (Theme: Defense)

The forced divorce case of Lu Yu and his wife is used to teach students that 'love is more solid than gold' and one is obliged to defend theirs and others' rights. Bounded by the traditional customs and the rejection of his mother, Lu Yu was unable to defend the marriage between him and his wife, and they were ultimately forced to separate. Nowadays, with every person having the same rights, when an individual executes his/her own rights, he/she should never invade or damage others' rights, and should defend against injustice.

Magpie Bridge (Theme: Maintenance)

A poem written based on the renowned Chinese mythology - the cowherd and the weaving girl who could only reunify once a year - describes the grief at their separation and joy in reunion [26]. This resonates with another poem written by Su Shi, in which he expressed his deep nostalgia towards parting with his younger brother [26]. Both poems urge youngsters to treasure the time with their beloved and maintain an intimate relationship with them.

Echo Valley (Theme: Confiding)

Students could acquire the skills of confiding and listening to others through ‘self-inspection’. Confucius admonished that “be strict with oneself and be lenient with others”, underscoring the need to constantly review our behavior and words in order to correct one’s mistake. Improvement in confiding skills ensures a harmonious relationship with peers.

Discussion: Enrichment of Knowledge through Literature and Games

It would be a challenge for students who do not have adequate knowledge regarding the historical background and social context of the authors to grasp the underlying meanings of their work. Therefore, to help students attain a better understanding on the fourteen core components, detailed explanation of the classics and poems are provided in the game. The provision of additional information - such as the feature, origin, and structure of parallel prose - is a precious opportunity for foreigners to be exposed to classical Chinese poetry which is different from western forms. Chinese poetry emphasizes “consistency in the number of words” and “neatness of lines”, fulfilling visual aesthetics and antithesis; whereas Western poems fail to achieve the same length of lines owing to the alphabetical constraint [35, p. 25]. The exposure of new knowledge might stimulate their interest and willingness to read more poetry and literature to build a long-term reading habit [36, p. 87]. Moreover, students could better understand the differences between Chinese and Western cultures and values. In terms of gender equality, traditional Chinese society defines equality as “always [being] courteous to each other like guests”, as being polite is the result of one’s self-respect and love to others [37]. Thus, one is reminded to treat their friends and loved ones wholeheartedly and respectfully. In contrast, western countries emphasize philanthropism, meaning the caring and respect for all individuals, not only one’s friends and loved ones [37]. Hence, they advocate everyone should enjoy equal rights and equality and offer help to the poor and the needy. Understanding the cultural differences could narrow the gap between people with different backgrounds, encouraging them to respect and build bonding with one another. After digesting huge amounts of Chinese and Western literature, mini-games are effective ways for youngsters to contemplate and put knowledge into practice, for instance, distinguishing between desirable and undesirable behaviors.

Favoring Personal Development

Literature encourages students to think from others’ perspectives, fostering the development of empathy and understanding which enable them to build strong bonding with others. Scholars agree fiction strengthens audience’s abilities to substitute themselves in another’s situation, bringing changes to their thoughts and emotions [38, p. 2]. Engagement with fiction stimulates the development of “Theory of Mind” [39], “the ability to detect and understand others’ emotions and the inference and representation of others’ beliefs and intentions”, leading to the cultivation of a sense of empathy and understanding (p. 377). Chiariello [40] also proposes encouraging of empathy and perspective taking, along with facilitating impersonal (thus rational) discussion, and providing models for character as the three social functions of fiction.

Table 1. Chinese and Western literature used for the fourteen core components

Station	Chinese literature	Western literature	Game element	Core quality of friendship
Mediation Sea	The characteristics of ideal personality affirmed by traditional Chinese culture	The characteristics of ideal personality affirmed by Western culture	Psychological test	Understanding self and a close friend
Tianping (Balance) Village	The amount of love given to your loved one should be mutually equal; Qin Jia felt sorry for not giving enough love to his wife, and instead he gave physical goods to his wife as recompense.	The true essence of love according to book of Corinthians from the Bible	Mini quiz on gender equality	Equality (Law-abiding / courteous)
Comfort Forest	Yu Boya became bosom friend with Zhong Ziqi as they appreciated each other's musical attainment and found connection in the pleasure of music.	Robert and Clara Schumann fell in love with each other due to their passion in music. Even after Robert's death, Clara continued to promote his work.	Making friends through arts and literature: A mini game on music production	Pleasure
Patience Mountain	Two high-ranking officials, Lin Xiangru and Lian Po, demonstrated willingness to put aside rancor and forgive each other.	A bag is used as a metaphor of hatred, implying the more attention Hercules pays on it, the greater the hatred expands. This shows the importance of forgiveness.	A short message on acceptance	Acceptance
Dedication Spring	The friendship of Guan Zhong and Bao Shuya manifests the importance of trust and willingness to sacrifice and devote oneself to another without demanding return.	Samuel Walton's unacceptance of any imperfection in his work demonstrated his great sense of sincerity, responsibility, and devotion.	A mini game on devotion to your loved ones	Devotion

Table 1. (Continued)

Station	Chinese literature	Western literature	Game element	Core quality of friendship
Thousand-hand cliff	Guan Ning ended the friendship with Hua Xin due to his inattentive attitude, but Guan's act was to assist Hua to reflect on the value behind his behaviors, hoping that he would make improvements.	Former American President Obama's considerate, humble and straightforward personality won the support of his wife, the mass and even his opponents.	A mini game testing how helpful the player is, with immediate feedback	Assistance
Heart-to-heart lake	The two short stories emphasize trust and the importance of keeping one's promise, including a high-ranking official's promise to citizens.	Damon was willing to trust his friend Pythias despite of impending death.	A metaphor of mathematics induction method to illustrate whether a person is trustworthy	Trust
Respect Lake	Confucius teaching stressed one should "look humble outside and be respectful inside", implying that respect to parents, friends and lovers has to come from the heart.	Norms of respect in Western societies such as attitude, respecting others' rights, courtesy towards teachers, seniors, classmates, at home, in public places, and maintaining personal appearance	Mini quiz on 90 randomly selected items on respect from 112 items in 1.5 minutes	Respect
Fidelity Rock	Study the lyrics of a Cantonese song	Read a modern short story on the companionship of two young lovers	Discussion questions provided	Loyalty
Awakening Rock	Two Chinese poems describing individuals having great ambition and open-minded confidence even after being relegated	A Western short story on the building blocks of self-esteem	Nil	Self-esteem
Symbiotic Wood	Confucius advocated a person's positive character is the most important consideration in choosing friends, instead of their social status or wealth.	A modern short story on mutual recognition and respect	A test on reciprocity with immediate feedback	Reciprocity
Jintang (Golden hot water) Brook	The forced divorce case of Lu Yu and his wife manifested that 'love is more solid than gold' and one is obliged to defend theirs and others' rights.	A passage to encourage the adoption of different perspectives to make moral decisions	Illustrations of moral decision making	Defense
Xique (Magpie) Bridge	A poem based on the renowned mythology - the cowherd and the weaving girl who could only reunify once a year - describes the grief at their separation and joy in reunion. Another poem written by Su Shi expresses his deep nostalgia towards parting with his younger brother.	A modern short story: Unable to accompany	Scenario-based questions	Maintenance
Echo Valley	Confucius teaching mentioned one should "be strict with oneself and be lenient with others", underscoring the need to constantly review our behavior and words in order to correct one's mistake.	Ancient and modern mottos are suggested, for instance, Jesus said, "There is no greater love than this: to lay down one's life for one's friends."	Scenario-based questions	Confiding

Through self-reflection on their ways of treating their friends, readers are reminded to self-modify their behaviors in order to become a considerate person, which would bring positive influences on their self-development and interpersonal relationship [38]. This echoes the findings of the Dutch Institute for Curriculum Development that literature education “has an important value for developing citizenship, broadening social and cultural horizons and developing empathic capabilities” [38, p. 2], in which readers would have a change in their inner self and attitude towards others. In addition, the fourteen essential elements are good examples of strategies to strengthen students’ bonding, “providing clear and consistent guidelines and expectations for adolescents to follow and maintain an intimate bonding with peers” [3, p. 6]. For instance, one should keep their promises faithfully to gain friends’ trust and respect, which is also the core for youngsters to become a person with great virtue and good reputation.

Enhancing Language Skills and the Expression of Emotions

Literature enhances youngsters’ emotional and behavioral competencies. Through the enlargement of readers’ vocabulary, their ability to express emotions and thoughts would be strengthened [17]. Confucius believed that, “Poetry serves to stimulate the mind. They may be used for purposes of self-contemplation. They teach the art of sociability. They show how to regulate feelings of resentment” [35, pp. 4-5]. Indeed, one could learn to cope with aversive emotions and distressing circumstances from literature, which could be illustrated with the story of Lin Xiangru and Lian Po (from Patience Mountain). When having conflicts, one should restrain his/her temper and show sincerity to communicate with one another in order to solve the crisis, as only understanding would bring forgiveness and foster a deeper relationship with peers [41].

STATION 7: LOVE ROAD STATION

To motivate students to use the material, the contents are delivered in the “Love Institute” where players can choose their majors and elective courses on the seven stages of a romantic relationship. *The Little Prince* is used to help students reflect on their own values and encourage a critical examination of their beliefs when encountering difficulties in the sixth stage – to decide whether to commit or to breakup. The book is one of the classics of all time that covers seven stages of a romantic relationship. It is on the list of The 10th Secondary School’s Best Ten Books Election in Hong Kong. Having a basic understanding of the storyline in mind, players would be able to develop an in-depth analysis and grasp the underlying meaning.

The Differences between Literature and Literature in Game

In literature, “the author’s intention’ and ‘the perspicacity of the ‘audience’” are both indispensable [42]. Yet the author’s intention, otherwise known as literary implications/

assertion, would often not be explicitly stated, which is called ‘secondary meanings’ or ‘depth meanings’. This leaves room for readers’ own interpretation and subjectivity, resulting in the varying understanding of the author’s intention [43]. Moreover, according to McDuffie [44], “literary authors are not letter-writers”, meaning they are not addressing a specific person but a wider spectrum of audience (p. 108). Thus, they have to adopt a rather universal expression and representation. As our target audience is mainly youngsters, it is possible that they might misread the stories, or be unable to grasp the underlying meanings and in turn the moral lesson owing to the lack of experience or knowledge. From the perspective of educators, there is a need to guide students to acknowledge the assertion that the author is trying to proclaim, and to emphasize those that align with our teaching goals. Take *The Little Prince* as an illustration: the question “why was the Little Prince so determined to leave the rose and let his beloved rose live on the asteroid alone” is first raised to stimulate discussion among teenagers [45, pp. 49-50]. One of the possible reasons is “the rose is not beautiful enough”, but the book actually mentions that “her beauty made it difficult for him to calm down, and he believed that the rose was the most stunning and unique flower in the universe”, meaning that it would not be the answer [45, pp. 49-50]. Another possibility is that “the Little Prince got bored”; yet it is unconvincing as “the Little Prince took care of the rose attentively and patiently until his departure”, implying that the rose meant a lot to him [45, pp. 49-50]. Indeed, the truth is “the Little Prince could not face the rose or himself”. They both loved each other deeply, but misunderstanding tore them apart [45, pp. 49-50]. Consequently, it is essential to list out all possible interpretations along with evidence and explanation in the game in order to help youngsters differentiate between right and wrong interpretations (in this case, right and wrong interpretations towards the one you love). By revealing the characters’ inner feelings, readers would be aware of the need to put themselves in others’ shoes and view an issue from multiple perspectives. They would be able to cultivate a sense of empathy towards friends and family and become a considerate individual [46].

The Function of Literature in Promoting PYD

Literature is believed to carry cognitive values through the communication of propositional knowledge, which puts the focus on conveying the actual knowledge and experience to readers. Mikkonen sees literature as a carrier of human knowledge and experience, and suggests that the knowledge obtained from literature is believed to be “knowledge of concepts, modal knowledge or knowledge of possibilities, knowledge of human nature or emotions” [46, p. 9]. Readers’ own knowledge and experience overlap with the author’s to various extents, helping them explore new experiences, broaden their horizons, and stimulate their imagination [46]. Mary Sirridge further elaborates on this point that literature has an educational function which “clarifies our knowledge of the actual world” [46, p. 10].

Literary truth is arguably different from scientific truth, which presents facts explicitly [46]. Therefore, readers are demanded to think thoroughly and even think from the author’s perspective to extract literary truth, since the moral lessons are hidden in between words [43]. For example, in *The Little Prince*, readers have to look for the meaning of love from the conversation between the fox and the boy. With the help of the explanation provided in the

game, one understands love “comes from one’s internal emotions” and the willingness to be another’s “the one and the only one” [45, pp. 67-69]. Through an in-depth reflection, students would foster a desirable cognitive change in their mind regarding the topic of love, which could not be learnt from ordinary textbooks or lessons in schools.

Educational Purposes of Literature (Behavioral Influence on Teenagers)

Pulido-Mantas and Ruiz-Seisdedos [47] quoted Soriano’s definition of children’s literature as “a literary and historical communication ... located in time and space between an adult speaker or writer, the sender, and a recipient child, being the receiver, and who by definition, only experiences part of the reality and the linguistic, intellectual, emotional, etc. structures that are characteristic of adulthood” [47, p. 33]. Text is described as a vehicle of communication, which serves as the bridge between readers and authors. Authors not only intend to “communicate a message”, but more importantly to “convey a sweep of experiences as they are lived, in every facet of their vivid, concrete, and unmediated complexity” [44, p. 108]. Literature is the accumulation of past knowledge and experience, enriching and guiding audience towards the correct path. For instance, ‘taming’ is one of the core topics in *The Little Prince*, in which the fox taught the boy ‘taming’ is to be the one and the only one in each other’s world and needing each other [45]. Therefore, one ought to be loyal and attentive to one’s partner, and be willing to spend time in caring and listening to their beloved’s needs. It is a precious lesson for teenagers to be prepared for starting a romantic relationship and learn the way of building harmonious relationships with others. Di Girolamo offers a good conclusion: “The social function of literature becomes fully manifest only where the reader’s literary experience enters into the horizon of expectations of his real life, shapes his understanding of the world, and therefore influences his social behavior” [48, p. 41]. Literature, like other educational activities, possesses the social function to guide youngsters to be a better person. In addition, literature has the power to encourage the audience to continue craving for knowledge, driving them to delve into other relevant literary texts/publications regarding the historical and social context of the fiction, which is in favor of the enrichment of knowledge [36].

Promote an Interactive Relationship between the Author and Readers

Instead of applying a top-down teaching approach, literature cultivates the audience’s response on an issue or hypothesis raised by the author, which fosters contemplation and verification [46]. From intrinsic to extrinsic, readers would relate back to their daily lives or own experience [46]. For example, in *The Little Prince*, the depiction of the breakup of the boy and the rose is not just meant to arouse sympathy, but also urges readers to ponder on the reasons behind which cause the tragedy, granting them the opportunity to contemplate and reflect on their behaviors. Recalling what they have learnt in the previous stations, for instance, the fourteen essential elements for building, maintaining and enhancing relationships would help them gradually apply knowledge into daily lives, such as cultivating

good qualities and dropping bad habits, and thus improve their well-being in order to be prepared for a new relationship.

Mental and Emotional Sensation/Resonance

Moral values and messages are conveyed through fables and stories as “tale is essential for gaining knowledge in a dynamic and playful way” [47, p. 35]. Stories stimulate readers’ imagination, helping readers visualize text into images, which is similar to a “cartoon story” [42]. According to Palmer [42], audience are “encouraged to ‘dwell in the experience’” which “conveys both the involvement and the detachment of our response to imagined situations” [42, p. 203]. With the aid of game-based learning, ‘transportation theory’ is applied where players are mentally transported into the fictional world [49]. This would potentially induce their empathy and engagement with the characters, as students might have been through similar situations [36]. For those who had experienced failure in relationships, they might understand the heartbreaking feeling when the Little Prince broke up with the rose. However, they could also find mental support and concrete suggestions in the game on ways of getting over the pain and moving on. Other than looking for another person to ‘tame’, a new way is to expand the conception of ‘tamelessness’, as the meaning of life is not restricted to romantic relationships. Youngsters are encouraged to pursue dreams or dedicate themselves to other meaningful activities [45].

CONCLUSION

To nurture adolescents on all the core components of building and maintaining PRR, self-understanding and empathetic understanding of others through values clarification and perspective taking are crucial. This game provides an effective means to achieve these through incorporating learning materials taken from Chinese and Western literature, with a higher proportion of the former due to the cultural background of the game designer. However, English translations are provided, which enables players from different cultural backgrounds to access the game. Although the game includes only Chinese and Western literature, it represents a thoughtful effort in promoting PYD among adolescents through integrating Chinese and Western ideas.

In a world of multi-ethnicity and cultural diversity, the game represents a small step in promoting mutual understanding and cross-cultural learning. Literature that reflects traditional Chinese cultural characteristics regarding the core components of peer and intimate relations are chosen. Selected from a vast range of literature in classical Chinese across different historical periods, this game also helps students explore the rich educational heritage and heterogeneous complexity of Chinese literature. English-speaking players may find it interesting to be exposed to many different forms of Chinese literacy and the values in traditional Chinese culture. This game can act both as a simulation of a PYD journey and an introduction to Chinese culture and literature.

The game can be incorporated into the curriculum of language, literature or translation studies for secondary school students from Chinese and Western cultural backgrounds or in a

cross-cultural classroom. By going through the game twice, following Chinese and Western literature respectively, students will be able to 1) understand the meaning of literature, especially the exploration of PRR; 2) be exposed to different literary styles, genres, and techniques of Chinese literature; and 3) learn core components of PRR through values of different cultures from various perspectives.

ACKNOWLEDGMENTS

The design and production of the seven digital games introduced in this book, the preparation of this work, and the Project P.A.T.H.S. were financially supported by *The Hong Kong Jockey Club Charities Trust*. Readers may request free copies for non-commercial purposes of these games by contacting Dr. TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This chapter is based with permission on a paper adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

Chapter 356

ELECTRONIC CIGARETTES: WHAT’S THE BOTTOM LINE?*

U.S. Department of Health and Human Services

- E-cigarettes have the potential to benefit adult smokers who are not pregnant if used as a complete substitute for regular cigarettes and other smoked tobacco products.
- E-cigarettes are not safe for youth, young adults, pregnant women, or adults who do not currently use tobacco products.
- While e-cigarettes have the potential to benefit some people and harm others, scientists still have a lot to learn about whether e-cigarettes are effective for quitting smoking.
- If you’ve never smoked or used other tobacco products or e-cigarettes, don’t start.

WHAT ARE E-CIGARETTES?

- E-cigarettes are known by many different names. They are sometimes called “e-cigs,” “e-hookahs,” “mods,” “vape pens,” “vapes,” “tank systems,” and “electronic nicotine delivery systems.”
- Some e-cigarettes are made to look like regular cigarettes, cigars, or pipes. Some resemble pens, USB sticks, and other everyday items.
- E-cigarettes produce an aerosol by heating a liquid that usually contains nicotine—the addictive drug in regular cigarettes, cigars, and other tobacco products—flavorings, and other chemicals that help to make the aerosol. Users inhale this aerosol into their lungs. Bystanders can also breathe in this aerosol when the user exhales into the air.
- E-cigarettes can be used to deliver marijuana and other drugs.

* This is an edited, reformatted and augmented version of the U.S. Department of Health and Human Services publication.

WHAT IS IN E-CIGARETTE AEROSOL?

The e-cigarette aerosol that users breathe from the device and exhale can contain harmful and potentially harmful substances:

It is difficult for consumers to know what e-cigarette products contain. For example, some e-cigarettes marketed as containing zero percent nicotine have been found to contain nicotine.

ARE E-CIGARETTES LESS HARMFUL THAN REGULAR CIGARETTES?

E-cigarette aerosol generally contains fewer toxic chemicals than the deadly mix of 7,000 chemicals in smoke from regular cigarettes. However, e-cigarette aerosol is not harmless. It can contain harmful and potentially harmful substances, including nicotine, heavy metals like lead, volatile organic compounds, and cancer-causing agents.

SCIENTISTS ARE STILL LEARNING ABOUT THE LONG-TERM HEALTH EFFECTS OF E-CIGARETTES. HERE IS WHAT WE KNOW NOW

Most e-cigarettes contain nicotine, which has known health effects.

- Nicotine is highly addictive.
- Nicotine is toxic to developing fetuses.
- Nicotine can harm adolescent brain development, which continues into the early to mid-20s.
- Nicotine is a health danger for pregnant women and their developing babies.

Besides nicotine, e-cigarette aerosol can contain substances that harm the body.

- This includes cancer-causing chemicals and tiny particles that reach deep into lungs. However, e-cigarette aerosol generally contains fewer harmful chemicals than smoke from burned tobacco products.

E-cigarettes can cause unintended injuries.

- Defective e-cigarette batteries have caused fires and explosions, some of which have resulted in serious injuries.

- In addition, acute nicotine exposure can be toxic. Children and adults have been poisoned by swallowing, breathing, or absorbing e-cigarette liquid.

CAN E-CIGARETTES HELP ADULTS QUIT SMOKING CIGARETTES?

E-CIGARETTES ARE NOT CURRENTLY APPROVED BY THE FDA AS A QUIT SMOKING AID

The U.S. Preventive Services Task Force, a group of health experts that makes recommendations about preventive health care, concluded that the evidence is insufficient to recommend e-cigarettes for smoking cessation in adults, including pregnant women.

HOWEVER, e-cigarettes may help non-pregnant adult smokers if used as a complete substitute for all cigarettes and other smoked tobacco products.

TO DATE, THE FEW STUDIES ON THE ISSUE ARE MIXED

Evidence from two randomized controlled trials found that e-cigarettes with nicotine can help smokers stop smoking in the long term compared with placebo (non-nicotine) e-cigarettes.

A recent CDC study found that many adults are using e-cigarettes in an attempt to quit smoking. However, most adult e-cigarette users do not stop smoking cigarettes and are instead continuing to use both products (“dual use”). Because smoking even a few cigarettes a day can be dangerous, quitting smoking completely is very important to protect your health.

WHO IS USING E-CIGARETTES?

Chapter 357

E-CIGARETTE USE AMONG YOUTH AND YOUNG ADULTS*

U.S. Department of Health and Human Services

MESSAGE FROM SYLVIA BURWELL

Secretary, U.S. Department of Health and Human Services

The mission of the Department of Health and Human Services is to enhance and protect the health and well-being of all Americans. This report confirms that the use of electronic cigarettes (or e-cigarettes) is growing rapidly among American youth and young adults. While these products are novel, we know they contain harmful ingredients that are dangerous to youth. Important strides have been made over the past several decades in reducing conventional cigarette smoking among youth and young adults. We must make sure this progress is not compromised by the initiation and use of new tobacco products, such as e-cigarettes. That work is already underway.

To protect young people from initiating or continuing the use of e-cigarettes, actions must be taken at the federal, state, and local levels. At the federal level, the U.S. Food and Drug Administration (FDA)—under authority granted to it by Congress under the Family Smoking Prevention and Tobacco Control Act of 2009—took a historic step to protect America’s youth from the harmful effects of using e-cigarettes by extending its regulatory authority over the manufacturing, distribution, and marketing of e-cigarettes. Through such action, FDA now requires minimum age restrictions to prevent sales to minors and prohibits sales through vending machines (in any facility that admits youth), and will require products to carry a nicotine warning.

We have more to do to help protect Americans from the dangers of tobacco and nicotine, especially our youth. As cigarette smoking among those under 18 has fallen, the use of other nicotine products, including e-cigarettes, has taken a drastic leap. All of this is creating a new generation of Americans who are at risk of nicotine addiction.

* This is an edited, reformatted and augmented version of U.S. Department of Health and Human Services, dated 2016.

The findings from this report reinforce the need to support evidence-based programs to prevent youth and young adults from using tobacco in any form, including e-cigarettes. The health and well-being of our nation's young people depend on it.

FOREWORD

Tobacco use among youth and young adults in any form, including e-cigarettes, is not safe. In recent years, e-cigarette use by youth and young adults has increased at an alarming rate. E-cigarettes are now the most commonly used tobacco product among youth in the United States. This timely report highlights the rapidly changing patterns of e-cigarette use among youth and young adults, assesses what we know about the health effects of using these products, and describes strategies that tobacco companies use to recruit our nation's youth and young adults to try and continue using e-cigarettes. The report also outlines interventions that can be adopted to minimize the harm these products cause to our nation's youth.

E-cigarettes are tobacco products that deliver nicotine. Nicotine is a highly addictive substance, and many of today's youth who are using e-cigarettes could become tomorrow's cigarette smokers. Nicotine exposure can also harm brain development in ways that may affect the health and mental health of our kids.

E-cigarette use among youth and young adults is associated with the use of other tobacco products, including conventional cigarettes. Because most tobacco use is established during adolescence, actions to prevent our nation's young people from the potential of a lifetime of nicotine addiction are critical.

E-cigarette companies appear to be using many of the advertising tactics the tobacco industry used to persuade a new generation of young people to use their products. Companies are promoting their products through television and radio advertisements that use celebrities, sexual content, and claims of independence to glamorize these addictive products and make them appealing to young people.

Comprehensive tobacco control and prevention strategies for youth and young adults should address all tobacco products, including e-cigarettes. Further reductions in tobacco use and initiation among youth and young adults are achievable by regulating the manufacturing, distribution, marketing, and sales of all tobacco products—including e-cigarettes, and particularly to children—and combining those approaches with other proven strategies. These strategies include funding tobacco control programs at levels recommended by the Centers for Disease Control and Prevention (CDC); increasing prices of tobacco products; implementing and enforcing comprehensive smokefree laws; and sustaining hard-hitting media campaigns, such as CDC's *Tips from Former Smokers* that encourages smokers to quit for good, and FDA's *Real Cost* that is aimed at preventing youth from trying tobacco and reducing the number of youth who move from experimenting to regular use. We can implement these cost-effective, evidence-based, life-saving strategies now. Together with additional effort and support, we can protect the health of our nation's young people.

Thomas R. Frieden, M.D., M.P.H.

Director

Centers for Disease Control and Prevention

PREFACE

From the Surgeon General

E-cigarette use among U.S. youth and young adults is now a major public health concern. E-cigarette use has increased considerably in recent years, growing an astounding 900% among high school students from 2011 to 2015. These products are now the most commonly used form of tobacco among youth in the United States, surpassing conventional tobacco products, including cigarettes, cigars, chewing tobacco, and hookahs. Most e-cigarettes contain nicotine, which can cause addiction and can harm the developing adolescent brain.

Compared with older adults, the brain of youth and young adults is more vulnerable to the negative consequences of nicotine exposure. The effects include addiction, priming for use of other addictive substances, reduced impulse control, deficits in attention and cognition, and mood disorders. Furthermore, fetal exposure to nicotine during pregnancy can result in multiple adverse consequences, including sudden infant death syndrome, altered corpus callosum, auditory processing deficits, effects on behaviors and obesity, and deficits in attention and cognition. Ingestion of e-cigarette liquids containing nicotine can also cause acute toxicity and possibly death if the contents of refill cartridges or bottles containing nicotine are consumed.

This report highlights what we know and do not know about e-cigarettes. Gaps in scientific evidence do exist, and this report is being issued while these products and their patterns of use continue to change quickly. For example, the health effects and potentially harmful doses of heated and aerosolized constituents of e-cigarette liquids—including solvents, flavorants, and toxicants—are not completely understood. However, although e-cigarettes generally emit fewer toxicants than combustible tobacco products, we know that aerosol from e-cigarettes is not harmless.

Although we continue to learn more about e-cigarettes with each passing day, we currently know enough to take action to protect our nation's young people from being harmed by these products. Previous reports of the Surgeon General have established that nearly all habitual tobacco use begins during youth and young adulthood. To prevent and reduce the use of e-cigarettes by youth and young adults, we must work together as a society. We must implement proven prevention and education strategies. Health care providers, parents, teachers, and other caregivers should advise youth about the dangers of nicotine and discourage tobacco use in any form, including e-cigarettes. They can set a positive example by being tobacco-free and encouraging those who already use these products to quit. Free help is available at 1-800-QUIT-NOW or <http://www.smokefree.gov>. Preventing tobacco use in any form among youth and young adults is critical to ending the tobacco epidemic in the United States.

Vivek H. Murthy, M.D., M.B.A.
U.S. Surgeon General

ACKNOWLEDGMENTS

This report was prepared by the U.S. Department of Health and Human Services under the general direction of the Centers for Disease Control and Prevention, National Center for Chronic Disease Prevention and Health Promotion, Office on Smoking and Health.

SECTION 1. INTRODUCTION, CONCLUSIONS, AND HISTORICAL BACKGROUND RELATIVE TO E-CIGARETTES

Introduction

Although conventional cigarette smoking has declined markedly over the past several decades among youth and young adults in the United States (U.S. Department of Health and Human Services [USDHHS] 2012), there have been substantial increases in the use of emerging tobacco products among these populations in recent years (Centers for Disease Control and Prevention [CDC] 2015c). Among these increases has been a dramatic rise in electronic cigarette (e-cigarette) use among youth and young adults. It is crucial that the progress made in reducing cigarette smoking among youth and young adults not be compromised by the initiation and use of e-cigarettes. This Surgeon General's report focuses on the history, epidemiology, and health effects of e-cigarette use among youth and young adults; the companies involved with marketing and promoting these products; and existing and proposed public health policies regarding the use of these products by youth and young adults.

Figure 1.1. Diversity of e-cigarette products.

E-cigarettes include a diverse group of devices that allow users to inhale an aerosol, which typically contains nicotine, flavorings, and other additives. E-cigarettes vary widely in design and appearance, but generally operate in a similar manner and are composed of similar components (Figure 1.1). A key challenge for surveillance of the products and understanding their patterns of use is the diverse and nonstandard nomenclature for the devices (Alexander et al. 2016). These devices are referred to, by the companies themselves, and by consumers, as “e-cigarettes,” “e-cigs,” “cigalikes,” “e-hookahs,” “mods,” “vape pens,” “vapes,” and “tank systems.” In this report, the term “e-cigarette” is used to represent all of the various products in this rapidly diversifying product category. The terms may differ by geographic region or simply by the prevailing preferences among young users. For example, some refer to all cigarette-shaped products as “e-cigarettes” or as “cigalikes,” and some may refer to the pen-style e-cigarettes as “hookah pens” or “vape pens” (Richtel 2014; Lempert et al. 2016).

This report focuses on research conducted among youth and young adults because of the implications of e-cigarette use in this population, particularly the potential for future public health problems. Understanding e-cigarette use among young persons is critical because previous research suggests that about 9 in 10 adult smokers first try conventional cigarettes during adolescence (USDHHS 2012). Similarly, youth e-cigarette experimentation and use could also extend into adulthood; however, e-cigarette use in this population has not been examined in previous reports of the Surgeon General. The first Surgeon General’s report on the health consequences of smoking was published in 1964; of the subsequent reports, those published in 1994 and 2012 focused solely on youth and young adults (USDHHS 1994, 2012). More recently, the 2012 report documented the evidence regarding tobacco use among youth and young adults, concluding that declines in cigarette smoking had slowed and that decreases in the use of smokeless tobacco had stalled. That report also found that the tobacco

industry's advertising and promotional activities are causal to the onset of smoking in youth and young adults and the continuation of such use as adults (USDHHS 2012). However, the 2012 report was prepared before e-cigarettes were as widely promoted and used in the United States as they are now. Therefore, this 2016 report documents the scientific literature on these new products and their marketing, within the context of youth and young adults. This report also looks to the future by examining the potential impact of e-cigarette use among youth and young adults, while also summarizing the research on current use, health consequences, and marketing as it applies to youth and young adults.

Evidence for this report was gathered from studies that included one or more of three age groups. We defined these age groups to be young adolescents (11–13 years of age), adolescents (14–17 years of age), and young adults (18–24 years of age). Some studies refer to the younger groups more generally as *youth*. Despite important issues related to e-cigarette use in adult populations, clinical and otherwise (e.g., their potential for use in conventional smoking cessation), that literature will generally not be included in this report unless it also discusses youth and young adults (Farsalinos and Polosa 2014; Franck et al. 2014; Grana et al. 2014).

Given the recency of the research that pertains to e-cigarettes, compared with the decades of research on cigarette smoking, the “precautionary principle” is used to guide actions to address e-cigarette use among youth and young adults. This principle supports intervention to avoid possible health risks when the potential risks remain uncertain and have been as yet partially undefined (Bialous and Sarma 2014; Saitta et al. 2014; Hagopian et al. 2015). Still, the report underscores and draws its conclusions from the known health risks of e-cigarette use in this age group.

Organization of the Report

This chapter presents a brief introduction to this report and includes its major conclusions followed by the conclusions of the chapters, the historical background of e-cigarettes, descriptions of the products, a review of the marketing and promotional activities of e-cigarette companies, and the current status of regulations from the U.S. Food and Drug Administration (FDA). Chapter 2 (“Patterns of E-Cigarette Use Among U.S. Youth and Young Adults”) describes the epidemiology of e-cigarette use, including current use (i.e., past 30 day); ever use; co-occurrence of using e-cigarettes with other tobacco products, like cigarettes; and psychosocial factors associated with using e-cigarettes, relying on data from the most recent nationally representative studies available at the time this report was prepared. Chapter 3 (“Health Effects of E-Cigarette Use Among U.S. Youth and Young Adults”) documents the evidence related to the health effects of e-cigarette use, including those that are associated with direct aerosol inhalation by users, the indirect health effects of e-cigarette use, other non-aerosol health effects of e-cigarette use, and secondhand exposure to constituents of the aerosol. Chapter 4 (“Activities of the E-Cigarette Companies”) describes e-cigarette companies’ influences on e-cigarette use and considers manufacturing and price; the impact of price on sales and use; the rapid changes in the industry, particularly the e-cigarette companies; and the marketing and promotion of e-cigarettes. Chapter 5 (“E-Cigarette Policy and Practice Implications”) discusses the implications for policy and practice at the national, state, and local levels. The report ends with a Call to Action to stakeholders—including policymakers, public health practitioners and clinicians, researchers, and the public—to work

to prevent harms from e-cigarette use and secondhand aerosol exposure among youth and young adults.

Preparation of This Report

This Surgeon General's report was prepared by the Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion, CDC, which is part of USDHHS. The initial drafts of the chapters were written by 27 experts who were selected for their knowledge of the topics addressed. These contributions are summarized in five chapters that were evaluated by approximately 30 peer reviewers. After peer review, the entire manuscript was sent to more than 20 scientists and other experts, who examined it for its scientific integrity. After each review cycle, the drafts were revised by the report's scientific editors on the basis of reviewers' comments. Subsequently, the report was reviewed by various institutes and agencies within USDHHS.

Scientific Basis of the Report

The statements and conclusions throughout this report are documented by the citation of studies published in the scientific literature. Publication lags have prevented an up-to-the-minute inclusion of all recently published articles and data. This overall report primarily cites peer-reviewed journal articles, including reviews that integrate findings from numerous studies and books that were published through December 2015. However, selected studies from 2016 have been added during the review process that provide further support for the conclusions in this report. When a cited study has been accepted for publication, but the publication has not yet occurred because of the delay between acceptance and final publication, the study is referred to as "in press." This report also refers, on occasion, to unpublished research, such as presentations at a professional meeting, personal communications from a researcher, or information available in various media. These references are employed when acknowledged by the editors and reviewers as being from reliable sources, which add to the emerging literature on a topic.

Major Conclusions

- 1) E-cigarettes are a rapidly emerging and diversified product class. These devices typically deliver nicotine, flavorings, and other additives to users via an inhaled aerosol. These devices are referred to by a variety of names, including "e-cigs," "e-hookahs," "mods," "vape pens," "vapes," and "tank systems."
- 2) E-cigarette use among youth and young adults has become a public health concern. In 2014, current use of e-cigarettes by young adults 18–24 years of age surpassed that of adults 25 years of age and older.
- 3) E-cigarettes are now the most commonly used tobacco product among youth, surpassing conventional cigarettes in 2014. E-cigarette use is strongly associated with the use of other tobacco products among youth and young adults, including combustible tobacco products.

- 4) The use of products containing nicotine poses dangers to youth, pregnant women, and fetuses. The use of products containing nicotine in any form among youth, including in e-cigarettes, is unsafe.
- 5) E-cigarette aerosol is not harmless. It can contain harmful and potentially harmful constituents, including nicotine. Nicotine exposure during adolescence can cause addiction and can harm the developing adolescent brain.
- 6) E-cigarettes are marketed by promoting flavors and using a wide variety of media channels and approaches that have been used in the past for marketing conventional tobacco products to youth and young adults.
- 7) Action can be taken at the national, state, local, tribal, and territorial levels to address e-cigarette use among youth and young adults. Actions could include incorporating e-cigarettes into smokefree policies, preventing access to e-cigarettes by youth, price and tax policies, retail licensure, regulation of e-cigarette marketing likely to attract youth, and educational initiatives targeting youth and young adults.

Chapter Conclusions

Chapter 1. Introduction, Conclusions, and Historical Background Relative to E-Cigarettes

- 1) E-cigarettes are devices that typically deliver nicotine, flavorings, and other additives to users via an inhaled aerosol. These devices are referred to by a variety of names, including “e-cigs,” “e-hookahs,” “mods,” “vape pens,” “vapes,” and “tank systems.”
- 2) E-cigarettes represent an evolution in a long history of tobacco products in the United States, including conventional cigarettes.
- 3) In May 2016, the Food and Drug Administration issued the deeming rule, exercising its regulatory authority over e-cigarettes as a tobacco product.

Chapter 2. Patterns of E-Cigarette Use among U.S. Youth and Young Adults

- 1) Among middle and high school students, both ever and past-30-day e-cigarette use have more than tripled since 2011. Among young adults 18–24 years of age, ever e-cigarette use more than doubled from 2013 to 2014 following a period of relative stability from 2011 to 2013.
- 2) The most recent data available show that the prevalence of past-30-day use of e-cigarettes is similar among high school students (16% in 2015, 13.4% in 2014) and young adults 18–24 years of age (13.6% in 2013–2014) compared to middle school students (5.3% in 2015, 3.9% in 2014) and adults 25 years of age and older (5.7% in 2013–2014).
- 3) Exclusive, past-30-day use of e-cigarettes among 8th-, 10th-, and 12th-grade students (6.8%, 10.4%, and 10.4%, respectively) exceeded exclusive, past-30-day use of conventional cigarettes in 2015 (1.4%, 2.2%, and 5.3%, respectively). In contrast—in 2013–2014 among young adults 18–24 years of age—exclusive, past-30-day use of conventional cigarettes (9.6%) exceeded exclusive, past-30-day use of e-cigarettes (6.1%). For both age groups, dual use of these products is common.

- 4) E-cigarette use is strongly associated with the use of other tobacco products among youth and young adults, particularly the use of combustible tobacco products. For example, in 2015, 58.8% of high school students who were current users of combustible tobacco products were also current users of e-cigarettes.
- 5) Among youth—older students, Hispanics, and Whites are more likely to use e-cigarettes than younger students and Blacks. Among young adults—males, Hispanics, Whites, and those with lower levels of education are more likely to use e-cigarettes than females, Blacks, and those with higher levels of education.
- 6) The most commonly cited reasons for using e-cigarettes among both youth and young adults are curiosity, flavoring/taste, and low perceived harm compared to other tobacco products. The use of e-cigarettes as an aid to quit conventional cigarettes is not reported as a primary reason for use among youth and young adults.
- 7) Flavored e-cigarette use among young adult current users (18–24 years of age) exceeds that of older adult current users (25 years of age and older). Moreover, among youth who have ever tried an e-cigarette, a majority used a flavored product the first time they tried an e-cigarette.
- 8) E-cigarette products can be used as a delivery system for cannabinoids and potentially for other illicit drugs. More specific surveillance measures are needed to assess the use of drugs other than nicotine in e-cigarettes.

Chapter 3. Health Effects of E-Cigarette Use among U.S. Youth and Young Adults

- 1) Nicotine exposure during adolescence can cause addiction and can harm the developing adolescent brain.
- 2) Nicotine can cross the placenta and has known effects on fetal and postnatal development. Therefore, nicotine delivered by e-cigarettes during pregnancy can result in multiple adverse consequences, including sudden infant death syndrome, and could result in altered corpus callosum, deficits in auditory processing, and obesity.
- 3) E-cigarettes can expose users to several chemicals, including nicotine, carbonyl compounds, and volatile organic compounds, known to have adverse health effects. The health effects and potentially harmful doses of heated and aerosolized constituents of e-cigarette liquids, including solvents, flavorants, and toxicants, are not completely understood.
- 4) E-cigarette aerosol is not harmless “water vapor,” although it generally contains fewer toxicants than combustible tobacco products.
- 5) Ingestion of e-cigarette liquids containing nicotine can cause acute toxicity and possibly death if the contents of refill cartridges or bottles containing nicotine are consumed.

Chapter 4. Activities of the E-Cigarette Companies

- 1) The e-cigarette market has grown and changed rapidly, with notable increases in total sales of e-cigarette products, types of products, consolidation of companies, marketing expenses, and sales channels.
- 2) Prices of e-cigarette products are inversely related to sales volume: as prices have declined, sales have sharply increased.

- 3) E-cigarette products are marketed in a wide variety of channels that have broad reach among youth and young adults, including television, point-of-sale, magazines, promotional activities, radio, and the Internet.
- 4) Themes in e-cigarette marketing, including sexual content and customer satisfaction, are parallel to themes and techniques that have been found to be appealing to youth and young adults in conventional cigarette advertising and promotion.

Chapter 5. E-Cigarette Policy and Practice Implications

- 1) The dynamic nature of the e-cigarette landscape calls for expansion and enhancement of tobacco-related surveillance to include (a) tracking patterns of use in priority populations; (b) monitoring the characteristics of the retail market; (c) examining policies at the national, state, local, tribal, and territorial levels; (d) examining the channels and messaging for marketing e-cigarettes in order to more fully understand the impact future regulations could have; and (e) searching for sentinel health events in youth and young adult e-cigarette users, while longer-term health consequences are tracked.
- 2) Strategic, comprehensive research is critical to identify and characterize the potential health risks from e-cigarette use, particularly among youth and young adults.
- 3) The adoption of public health strategies that are pre-cautionary to protect youth and young adults from adverse effects related to e-cigarettes is justified.
- 4) A broad program of behavioral, communications, and educational research is crucial to assess how youth perceive e-cigarettes and associated marketing messages, and to determine what kinds of tobacco control communication strategies and channels are most effective.
- 5) Health professionals represent an important channel for education about e-cigarettes, particularly for youth and young adults.
- 6) Diverse actions, modeled after evidence-based tobacco control strategies, can be taken at the state, local, tribal, and territorial levels to address e-cigarette use among youth and young adults, including incorporating e-cigarettes into smoke-free policies; preventing the access of youth to e-cigarettes; price and tax policies; retail licensure; regulation of e-cigarette marketing that is likely to attract youth and young adults, to the extent feasible under the law; and educational initiatives targeting youth and young adults. Among others, research focused on policy, economics, and the e-cigarette industry will aid in the development and implementation of evidence-based strategies and best practices.

Historical Background

Understanding the role of e-cigarettes requires understanding the long history of tobacco use in the United States, including the role of nicotine delivery, the multiple examples of “reduced-harm” products and associated health claims, and the impact of using tobacco products on the public’s health. Since the late nineteenth century, when the “modern” cigarette came into use, scientists and public health officials have linked cigarette smoking to a remarkable number of adverse effects, and it is now recognized as the primary cause of

premature death in the United States (USDHHS 2014). Correspondingly, for a century, manufacturers, scientists, entrepreneurs, and public health leaders have promoted or recommended product changes that might remove some of the harmful elements in cigarette smoke. E-cigarettes are among the latest products.

E-cigarettes are designed for users to inhale nicotine, flavorings, and other additives through an aerosol. The claims and marketing strategies employed by the e-cigarette companies, and the efforts made by others to develop scientific and regulatory tools to deal with these new products, both contribute to the current discourse on e-cigarettes. Many lessons for assessing the potential (and future) consequences of these products can be learned from examining the relevant experiences of the past century, especially the introduction of novel products (including e-cigarettes as well as other tobacco and nicotine products) and the claims of reduced exposure to toxins made by the industry and elsewhere.

Early Efforts to Modify Cigarettes

In the 1880s and 1890s, entrepreneurs promoted novel products that allegedly blocked nicotine and other constituents of conventional cigarettes believed to be poisonous. Dr. Scott's Electric Cigarettes, advertised in *Harper's Weekly*, claimed not only to light without matches but also to contain a cotton filter that "strains and eliminates the injurious qualities from the smoke," including nicotine (*Harper's Weekly* 1887). Nicotine delivery was essential to the development of the modern cigarette in the twentieth century; early on, this substance was thought to be addicting and thus vital to retaining customers. In 1913, the Camel brand was a new kind of cigarette that introduced high-nicotine content by using burley tobacco, which was generally too harsh to inhale into the lungs, but was made more inhalable through the addition of casings (e.g., sugars, licorice) (Tindall 1992; Proctor 2011). In 1916, American Tobacco introduced its Lucky Strike blended cigarette, and in 1918 Liggett & Myers (L&M) reformulated its Chesterfield brand to make it more palatable to users. As the market grew, advertisements for major brands routinely included health-related statements and testimonials from physicians. During the 1930s and 1940s, prominent advertising campaigns included claims like "Not a cough in a carload" (Old Gold) (Federal Trade Commission [FTC] 1964, p. LBA-5); "We removed from the tobacco harmful corrosive ACRIDS (pungent irritants) present in cigarettes manufactured in the old-fashioned way" (Lucky Strike) (FTC 1964, p. LBA-2); and "Smoking Camels stimulates the natural flow of digestive fluids ... increases alkalinity" (Camel) (FTC 1964, p. LBA-1a). Thus, early modifications to the cigarette were made so that it was more palatable, had a higher nicotine delivery and uptake, and could be marketed as "safe" (FTC 1964; Calfee 1985).

Filters, Tar Reduction, and Light and Low-Tar Cigarettes

The landmark 1964 Surgeon General's report on smoking and health concluded that cigarette smoking contributed substantially to mortality from certain specific diseases, including lung cancer (U.S. Department of Health, Education, and Welfare 1964). Although the 1964 report considered the topic, it found the evidence insufficient to assess the potential health benefits of cigarette filters. Cigarettes with filters became the norm by the 1960s, and marketing them with an overt message about harm reduction became the standard (National Cancer Institute [NCI] 1996). However, the Surgeon General convened another group of experts on June 1, 1966, to review the evidence on the role played by the tar and nicotine content in health. The group concluded that "[t]he preponderance of scientific evidence

strongly suggests that the lower the ‘tar’ and nicotine content of cigarette smoke, the less harmful are the effects” (Horn 1966, p. 16,168). Subsequent studies have repeatedly failed to demonstrate health benefits of smoking light and low-tar cigarettes versus full-flavor cigarettes (Herning et al. 1981; Russell et al. 1982; Benowitz et al. 1983, NCI 2001).

Over the years, the tobacco industry used multiple methods to reduce the machine-tested yields of tar and nicotine in cigarettes as a way to claim “healthier” cigarettes. Beginning in the 1970s, tobacco companies advertised the tar and nicotine levels for their cigarettes, which encouraged smokers to believe, without substantiation, they could reduce their risk of exposure to these constituents (Cummings et al. 2002; Pollay and Dewhirst 2002). In 1996, the FTC issued a statement that it would allow cigarette companies to include statements about tar and nicotine content in their advertising as long as they used a standardized machine-testing method (Peeler 1996).

The Role of Nicotine and Nicotine Delivery

Although the public health community understood early on that nicotine was the primary psychoactive ingredient in cigarette smoke, before the 1980s, little was known about the importance of nicotine in the addiction process beyond what the cigarette manufacturers had learned from their own research. Some scientists warned that due to nicotine addiction, a reduction in nicotine yields, along with decreases in tar, could lead smokers to change their smoking behavior, such as by smoking a greater number of cigarettes to maintain their nicotine intake or changing their behavior in more subtle ways, such as varying the depth of inhalation or smoking more of the cigarette (Jarvis et al. 2001; National Cancer Institute 2001; Thun and Burns 2001). Not until the 1970s and 1980s, as researchers studying other forms of drug abuse began to apply their research methods to cigarette smoking, did it become apparent that nicotine was similar in its addictive capability to other drugs of abuse, such as heroin and cocaine (USDHHS 1981, 1988). As described in the 1988 Surgeon General’s report and in subsequent research, symptoms associated with nicotine addiction include craving, withdrawal, and unconscious behaviors to ensure consistent intake of nicotine (USDHHS 1988; al’Absi et al. 2002; Hughes 2007).

Although the tobacco industry has long understood the importance of nicotine to maintain long-term cigarette smokers through addiction, public health officials did not fully appreciate this in a broad sense until the 1988 Surgeon General’s report, *The Health Consequences of Smoking: Nicotine Addiction* (USDHHS 1988).

FDA and Nicotine Regulation

In 1988 (and again in 1994), the Coalition on Smoking OR Health and other public-interest organizations petitioned FDA to classify low-tar and nicotine products as drugs and to classify Premier, the short-lived “smokeless cigarette product” from R.J. Reynolds, as an alternative nicotine-delivery system (Stratton et al. 2001). The Coalition on Smoking OR Health cited indirect claims made through advertising and marketing as evidence of R. J. Reynolds’s intent to have the product used for the mitigation or prevention of disease (Slade and Ballin 1993). Meanwhile, FDA launched an investigation into the practices of the tobacco industry, including the manipulation of nicotine delivery. FDA asserted its jurisdiction over cigarettes and smokeless tobacco and issued certain rules governing access to and promotion of these products (*Federal Register* 1996). On March 21, 2000, the U.S. Supreme Court ruled 5-4 that Congress had not yet given FDA the necessary statutory authority to issue any rules

pertaining to tobacco products (Gottlieb 2000; *FDA v. Brown & Williamson Tobacco Corp.* 2000). The subsequent debate over control of nicotine products, including their potential impact on youth, ultimately led to the passage of the 2009 *Family Smoking Prevention and Tobacco Control Act*, which gave FDA authority to regulate tobacco products. Thus, discussions about the introduction of novel nicotine-containing tobacco products in the market during the 1980s and 1990s helped shape the current regulation of tobacco and nicotine products.

New products introduced in the 1990s or later included modified tobacco cigarettes (e.g., Advance, Omni); cigarette-like products, also called cigalikes (e.g., Eclipse, Accord); and smokeless tobacco products (e.g., Ariva, Exalt, Revel, snus). Advance, made by Brown and Williamson, was test-marketed with the slogan “All of the taste ... Less of the toxins.” Vector launched a national advertising campaign for its Omni cigarette with the slogan “Reduced carcinogens. Premium taste.” In addition to the question of whether the claims were supported by sufficient evidence, scientists and tobacco control leaders raised concerns about the potential for adverse consequences associated with novel nicotine and tobacco products marketed for harm reduction, such as a reduction in cessation rates or increased experimentation by children (Warner and Martin 2003; Joseph et al. 2004; Caraballo et al. 2006). Studies have shown that smokers are interested in trying novel “reduced-exposure” products and perceive them to have lower health risks, even when advertising messages do not make explicit health claims (Hamilton et al. 2004; O’Connor et al. 2005; Caraballo et al. 2006; Choi et al. 2012; Pearson et al. 2012).

At FDA’s request, the Institute of Medicine (IOM [now the National Academy of Medicine]) convened a committee of experts to formulate scientific methods and standards by which potentially reduced-exposure products (PREPs), whether the purported reduction was pharmaceutical or tobacco related, could be assessed. The committee concluded that “[f]or many diseases attributable to tobacco use, reducing risk of disease by reducing exposure to tobacco toxicants is feasible” (Stratton et al. 2001, p. 232). However, it also cautioned that “PREPs have not yet been evaluated comprehensively enough (including for a sufficient time) to provide a scientific basis for concluding that they are associated with a reduced risk of disease compared to conventional tobacco use” (Stratton et al. 2001, p. 232). The committee added that “the major concern for public health is that tobacco users who might otherwise quit will use PREPs instead, or others may initiate smoking, feeling that PREPs are safe. That will lead to less harm reduction for a population (as well as less risk reduction for that individual) than would occur without the PREP, and possibly to an adverse effect on the population” (Stratton et al. 2001, p. 235). Subsequently, in 2006, Judge Kessler cited these findings in her decision which demanded the removal of light and low-tar labeling due to the misleading nature of these claims (*United States v. Philip Morris* 2006).

The E-Cigarette

Invention of the E-Cigarette

An early approximation of the current e-cigarette appeared in a U.S. patent application submitted in 1963 by Herbert A. Gilbert and was patented in August 1965 (U.S. Patent No. 3,200,819) (Gilbert 1965). The application was for a “smokeless nontobacco cigarette,” with the aim of providing “a safe and harmless means for and method of smoking” by replacing

burning tobacco and paper with heated, moist, flavored air. A battery-powered heating element would heat the flavor elements without combustion (Gilbert 1965). The Favor cigarette, introduced in 1986, was another early noncombustible product promoted as an alternative nicotine-containing tobacco product (United Press International 1986; Ling and Glantz 2005).

The first device in the recent innovation in e-cigarettes was developed in 2003 by the Chinese pharmacist Hon Lik, a former deputy director of the Institute of Chinese Medicine in Liaoning Province. Lik's patent application described a kind of electronic atomizing cigarette (Hon 2013). With support from Chinese investors, in 2004 the product was introduced on the Chinese market under the company name Ruyan (Sanford and Goebel 2014). The product gained some attention among Chinese smokers early on as a potential cessation device or an alternative cigarette product.

The e-cigarette was part of the U.S. market by the mid-2000s, and by 2010 additional brands started to appear in the nation's marketplace, including Ruyan and Janty (Regan et al. 2013). Ruyan gained a U.S. patent for its product with the application stating that the product is "an electronic atomization cigarette that functions as substitutes (sic) for quitting smoking and cigarette substitutes." (U.S. Patent No. 8,490,628 B2, 2013). In August 2013, Imperial Tobacco Group purchased the intellectual property behind the Ruyan e-cigarette for \$75 million. As of 2014 an estimated 90% of the world's production of e-cigarette technology and products came from mainland China, mainly Guangdong Province and Zhejiang Province (Barboza 2014).

Sales of e-cigarettes in the United States have risen rapidly since 2007. Widespread advertising via television commercials and through print advertisements for popular brands, often featuring celebrities, has contributed to a large increase in e-cigarette use by both adults and youth since 2010 (Felberbaum 2013; King et al. 2013; Regan et al. 2013). Additionally, marketing through social media, as well as other forms of Internet marketing, has been employed to market these devices (Huang et al. 2014; Kim et al. 2014).

In 2013, an estimated 13.1 million middle school and high school students were aware of e-cigarettes (Wang et al. 2014). According to data from the National Youth Tobacco Survey, in 2011 the prevalence of current e-cigarette use (defined as use during at least 1 day in the past 30 days) among high school students was 1.5%; prevalence increased dramatically, however, to 16% by 2015, surpassing the rate of conventional-cigarette use among high school students (CDC 2016b; see Chapter 2). This equates to 2.4 million high school students and 620,000 middle school students having used an e-cigarette at least one time in the past 30 days in 2015 (CDC 2016b).

These trends have led to substantial concern and discussion within public health communities, including state and national public health agencies, professional organizations, and school administrators and teachers. A primary concern is the potential for nicotine addiction among nonsmokers, especially youth and young adults, and that this exposure to nicotine among youth and young adults is harmful. The diversity and novelty of e-cigarette products on the market and ongoing product innovations make assessments of the biological effects of current e-cigarettes under actual conditions of use—such as their long-term harmfulness—difficult to measure. Unanswered questions remain about the risk profile of these devices, their potential use by young people as a first step to other nicotine products, and their total impact on public health. There are diverging opinions about the potential public health impact of these new products. Some public health scientists have highlighted the

potential for alternative nicotine products to serve as a substitute for conventional cigarettes and thus a harm reduction tool (Henningfield et al. 2003; Abrams 2014). Others have cautioned that the use of alternative nicotine products might become a bridge that may lead to greater tobacco product use—including dual or multiple-product use—or initiate nicotine addiction among nonsmokers, especially youth (Cobb et al. 2010; Wagener et al. 2012; Benowitz and Goniewicz 2013; Britton 2013; Chapman 2013; Etter 2013; USDHHS 2014). Current evidence is insufficient to reject either of these hypotheses.

E-Cigarette Products

Components and Devices

E-cigarette devices are composed of a battery, a reservoir for holding a solution that typically contains nicotine, a heating element or an atomizer, and a mouthpiece through which the user puffs (Figure 1.2). The device heats a liquid solution (often called e-liquid or e-juice) into an aerosol that is inhaled by the user. E-liquid typically uses propylene glycol and/or glycerin as a solvent for the nicotine and flavoring chemicals.

Flavors and E-Cigarettes

The e-liquids in e-cigarettes are most often flavored; a study estimated that 7,700 unique flavors exist (Zhu et al. 2014) and that most of them are fruit or candy flavors (Figure 1.3). A content analysis of the products available via online retail websites documented that tobacco, mint, coffee, and fruit flavors were most common, followed by candy (e.g., bubble gum), unique flavors (e.g., Belgian waffle), and alcoholic drink flavors (e.g., strawberry daiquiri) (Grana and Ling 2014). Some retail stores are also manufacturers that create custom flavors, which increases the variety of flavors available.

The widespread availability and popularity of flavored e-cigarettes is a key concern regarding the potential public health implications of the products. The concern, among youth, is that the availability of e-cigarettes with sweet flavors will facilitate nicotine addiction and simulated smoking behavior—which will lead to the use of conventional tobacco products (Kong et al. 2015; Krishnan-Sarin et al. 2015). Flavors have been used for decades to attract youth to tobacco products and to mask the flavor and harshness of tobacco (USDHHS 2012). Industry documents show that tobacco companies marketed flavored little cigars and cigarillos to youth and to African Americans to facilitate their uptake of cigarettes (Kostygina et al. 2014). Companies also intended flavored smokeless tobacco products to facilitate “graduation” to unflavored products that more easily deliver more nicotine to the user (USDHHS 2012). Various studies have shown that youth are more likely than adults to choose flavored cigarettes and cigars (CDC 2015b). Concern over these findings led Congress to include a ban on characterizing flavors for cigarettes, other than tobacco or menthol, in the Tobacco Control Act. A similar concern exists about e-cigarettes, and this concern is supported by studies indicating that youth and young adults who have ever used e-cigarettes begin their use with sweet flavors rather than tobacco flavors (Kong et al. 2015; Krishnan-Sarin et al. 2015). Notably, 81.5% of current youth e-cigarette users said they used e-cigarettes “because they come in flavors I like” (Ambrose et al. 2015).

E-Cigarette Devices

First-generation e-cigarettes were often similar in size and shape to conventional cigarettes, with a design that also simulated a traditional cigarette in terms of the colors used (e.g., a white body with tan mouthpiece). These devices were often called cigalikes, but there were other products designed to simulate a cigar or pipe. Other cigalikes were slightly longer or narrower than a cigarette; they may combine white with tan or may be black or colored brightly. These newer models use a cartridge design for the part of the device that holds the e-liquid, which is either prefilled with the liquid or empty and ready to be filled. The user then squeezes drops of the e-liquid onto a wick (or bit of cotton or polyfil) connected to the heating element and atomizer (Figure 1.4). As e-cigarettes have become more popular, their designs have become more diverse, as have the types of venues where they are sold (Noel et al. 2011; Zhu et al. 2014).

Figure 1.2. Parts of an e-cigarette device.

Second-generation devices include products that are shaped like pens, are comparatively larger and cylindrical, and are often referred to as “tank systems” in a nod to the transparent reservoir that holds larger amounts of e-liquid than previous cartridge-containing models. Third- and fourth-generation devices represent a diverse set of products and, aesthetically, constitute the greatest departure from the traditional cigarette shape, as many are square or

rectangular and feature customizable and rebuildable atomizers and batteries. In addition, since the beginning of the availability of e-cigarettes and their component parts, users have been modifying the devices or building their own devices, which are often referred to as “mods.” The differences in design and engineering of the products are key factors in the size, distribution, and amount of aerosol particles and the variability in levels of chemicals and nicotine present in the e-liquid/aerosol and delivered to the user (Brown and Cheng 2014).

E-Cigarette Product Components and Risks

One of the primary features of the more recent generation of devices is that they contain larger batteries and are capable of heating the liquid to a higher temperature, potentially releasing more nicotine, forming additional toxicants, and creating larger clouds of particulate matter (Bhatnagar et al. 2014; Kosmider et al. 2014). For instance, one study demonstrated that, at high temperatures (150°C), exceedingly high levels of formaldehyde—a carcinogen (found to be 10 times higher than at ambient temperatures)—are present that are formed through the heating of the e-liquid solvents (propylene glycol and glycerin), although the level of tolerance of actual users to the taste of the aerosol heated to this temperature is debated (Kosmider et al. 2014; CDC 2015a; Flavor and Extract Manufacturers Association of the United States 2015; Pankow et al. 2015). There is also concern regarding the safety of inhaling e-cigarette flavorings. Although some manufacturers have claimed their flavorants are generally recognized as safe for food additives (i.e., to be used in preparing foods for eating), little is known about the long-term health effects of inhaling these substances into the lungs (CDC 2015a).

Many devices can be readily customized by their users, which is also leading to the concern that these devices are often being used to deliver drugs other than nicotine (Brown and Cheng 2014). Most commonly reported in the news media, on blogs, and by user anecdote is the use of certain types of e-cigarette-related products for delivering different forms of marijuana (Morean et al. 2015; Schauer et al. 2016). The tank systems, for example, have been used with liquid tetrahydrocannabinol (THC) or hash oil. Some personal vaporizer devices can be used with marijuana plant material or a concentrated resin form of marijuana called “wax.” One study describes the use, in Europe, of e-cigarette devices to smoke marijuana (Etter 2015).

The various e-cigarette products, viewed as a group, lack standardization in terms of design, capacity for safely holding e-liquid, packaging of the e-liquid, and features designed to minimize hazards with use (Yang et al. 2014). All of these design features may have implications for the health impact of e-cigarette use. Notably, from 2010 to 2014, calls to poison control centers in the United States about exposures related to e-cigarettes increased dramatically. According to the American Association of Poison Control Centers (2015), 271 cases were reported in 2011, but 3,783 calls were reported in 2014. Among all calls, 51% involved exposure among children younger than 5 years of age (CDC 2014). Most poisonings appear to have been caused by exposure to nicotine-containing liquid (CDC 2014). The lack of a requirement for child-resistant packaging for e-liquid containers may have contributed to these poisonings. Since these data were released, one death in the United States has been confirmed in a child who drank e-liquid containing nicotine (Mohney 2014). Additionally, serious adverse reactions, including at least two deaths, have been reported to FDA in cases that could be attributed to the use of e-cigarettes (FDA 2013). This increase in poisonings prompted the *Child Nicotine Poisoning Prevention Act of 2015* (2016), which was enacted in January 2016. This law requires any container of liquid nicotine that is sold, manufactured, distributed, or imported into the United States to be placed in packaging that is difficult to open by children under 5 years of age.

Secondary risks are also of concern regarding e-cigarettes, including passive exposure to nicotine and other chemicals, and adverse events due to device malfunction. Nicotine is a neuroteratogen, and its use by pregnant women exposes a developing fetus to risks that are well documented in the 50th-anniversary Surgeon General’s report on smoking (USDHHS 2014) and include impaired brain development (England et al. 2015) and other serious consequences. Finally, another consequence of the lack of device regulation is the occurrence of battery failures and subsequent explosions. Explosions have typically occurred during charging, resulting in house and car fires, and sometimes causing injuries to those involved. From 2009 to late 2014, 25 incidents of explosions and fires involving e-cigarettes occurred in the United States (Chen 2013; U.S. Fire Administration 2014; FDA 2013).

E-Cigarette Companies

E-cigarette companies include manufacturers, wholesalers, importers, retailers, distributors, and some other groups that overlap with these entities (Barboza 2014; Whelan 2015). Currently, most of the products are manufactured in Shenzhen, Guangdong Province, China (Cobb et al. 2010; Grana et al. 2014; Zhu et al. 2014). One study placed the number of

brands at 466 in January 2014 and found a net increase of 10.5 brands per month (Zhu et al. 2014). All the major tobacco companies (e.g., Reynolds American, Altria; Table 1.1) and many smaller, independent companies are now in the business. When e-cigarettes first entered the U.S. market, they were sold primarily by independent companies via the Internet and in shopping malls at kiosks where those interested could sample the products. A unique feature of the e-cigarette industry, compared to other tobacco and nicotine products, is the recruitment of visitors to their websites as “affiliates” or distributors to help market the products and, in turn, receive commissions on sales (Grana and Ling 2014; Cobb et al. 2015). For example, some companies offer a way for users to earn a commission by advertising the products (e.g., a banner ad is placed on one’s website, and when someone clicks on the link and subsequently purchases a product, the website owner gets a percentage commission). Some companies also offer rewards programs for recruiting new customers or for brand loyalty, with web-site users earning points for free or reduced-price products (Richardson et al. 2015).

E-cigarettes are now in widespread national distribution through convenience stores, tobacco stores, pharmacies, “big box” retail chains such as Costco, online retailers, and shops devoted to e-cigarette products (often called “vape shops”) (Giovenco et al. 2015; Public Health Law Center 2015). The “vape shops” offer a place to buy customizable devices and e-liquid solutions in many flavors and sometimes include a café or other elements that promote socializing, essentially making such places like a lounge. With the rapid increase in distribution and marketing in the industry, sales have increased rapidly and were projected to reach \$2.5 billion in 2014 and \$3.5 billion in 2015, including projections for retail and online channels, as well as “vape shops” (Wells Fargo Securities 2015).

Table 1.1. Multinational tobacco companies with e-cigarette brands

Company	E-cigarette brand
Altria (NuMark)	MarkTen, Green Smoke
Philip Morris International	Heat-not-burn, IQOS brand (Vape Ranks 2014) E-cigs, Nicolites by Nicocigs (Philip Morris International 2014)
Reynolds (Reynolds Vapor Company)	VUSE
Lorillard (Lorillard Vapor Company)	blu (until 2015)
Imperial Tobacco (Fontem Ventures)	Puritane (formerly Ruyan) blu (acquired in 2015)
British American Tobacco	Vype
Swisher	E-swisher
Japan Tobacco International (JTI)	E-Lites, offered in the United Kingdom by Zandera Ltd., which was acquired by Japan Tobacco Inc. in 2014 (Japan Tobacco Inc. 2014) Ploom (tobacco pods in heat-not-burn) and Ploom PAX (used for vaporizing marijuana) (Japan Tobacco Inc. 2015)

The advertising and marketing of e-cigarette products has engendered skepticism among public health professionals and legislators, who have noted many similarities to the advertising claims and promotional tactics used for decades by the tobacco industry to sell conventional tobacco products (Campaign for Tobacco-Free Kids 2013; CDC 2016a). Indeed, several of the e-cigarette marketing themes have been reprised from the most memorable cigarette advertising, including those focused on freedom, rebellion, and glamor (Grana and Ling 2014). E-cigarette products are marketed with a variety of unsubstantiated health and cessation messages, with some websites featuring videos of endorsements by physicians

(another reprisal of old tobacco industry advertising) (Grana and Ling 2014; Zhu et al. 2014). Unlike conventional cigarettes, for which advertising has been prohibited from radio and television since 1971, e-cigarette products are advertised on both radio and television, with many ads featuring celebrities. E-cigarettes also are promoted through sports and music festival sponsorships, in contrast to conventional cigarettes and smokeless tobacco products, which have been prohibited from such sponsorships since the Master Settlement Agreement in 1998. E-cigarettes also appear as product placements in television shows and movies (Grana et al. 2011; Grana and Ling 2014).

Another key avenue for e-cigarette promotion is social media, such as Twitter, Facebook, YouTube, and Instagram. As is true in the tobacco industry, the e-cigarette industry organizes users through advocacy groups (Noel et al. 2011; Harris et al. 2014; Saitta et al. 2014; Caponnetto et al. 2015). The extensive marketing and advocacy through various channels broadens exposure to e-cigarette marketing messages and products; such activity may encourage nonsmokers, particularly youth and young adults, to perceive e-cigarette use as socially normative. The plethora of unregulated advertising is of particular concern, as exposure to advertising for tobacco products among youth is associated with cigarette smoking in a dose-response fashion (USDHHS 2012).

Federal Regulation of E-Cigarettes

A “Two-Pronged” Approach to Comprehensive Tobacco Control

Since the passage of the Tobacco Control Act in 2009, FDA has had the authority to regulate the manufacturing, distribution, and marketing of tobacco products sold in the United States. FDA had immediate jurisdiction over cigarettes, roll-your-own cigarette tobacco, and smokeless tobacco. In May 2016, FDA asserted jurisdiction over products that meet the statutory definition of a tobacco product, including e-cigarettes, except accessories of these products (*Federal Register* 2016). That regulation is currently under litigation.

The IOM’s 2007 report, *Ending the Tobacco Problem: A Blueprint for the Nation*, established a “two-pronged” strategy for comprehensive tobacco control: (1) full implementation of proven, traditional tobacco control measures such as clean indoor air laws, taxation, and countermarketing campaigns; and (2) “strong federal regulation of tobacco products and their marketing and distribution” (Bonnie et al. 2007, p. 1).

Included in FDA’s broad authority are the restriction of marketing and sales to youth, requiring disclosure of ingredients and harmful and potentially harmful constituents, setting product standards (e.g., requiring the reduction or elimination of ingredients or constituents), requiring premarket approval of new tobacco products and review of modified-risk tobacco products, and requiring health warnings. The standard for FDA to use many of its regulatory authorities is whether such an action is appropriate for the protection of public health (*Federal Food, Drug, and Cosmetic Act*, § 907(a)(3)(A)). The public health standard in the Tobacco Control Act also requires FDA to consider the health impact of certain regulatory actions at both the individual and population levels, including their impact on nonusers, and on initiation and cessation (*Federal Food, Drug, and Cosmetic Act*, § 907(a)(3)(B)).

Importantly, the Tobacco Control Act preserves the authority of state, local, tribal, and territorial governments to enact any policy “in addition to, or more stringent than”

requirements established under the Tobacco Control Act “relating to or prohibiting the sale, distribution, possession, exposure to, access to, advertising and promotion of, or use of tobacco products by individuals of any age” (*Federal Food, Drug, and Cosmetic Act*, § 916(a)(1)). This preservation of state and local authority ensures the continuation of more local-level, comprehensive tobacco control. However, the statute expressly preempts states and localities from establishing or continuing requirements that are different from or in addition to FDA requirements regarding standards for tobacco products, premarket review, adulteration, misbranding, labeling, registration, good manufacturing practices, or modified-risk tobacco products (*Federal Food, Drug, and Cosmetic Act*, § 916(a)(2)(A)). But this express preemption provision does not apply to state and local authority to impose requirements relating to the “sale, distribution, possession, information reporting to the State, exposure to, access to, the advertising and promotion of, or use of, tobacco products by individuals of any age . . .” (*Federal Food, Drug, and Cosmetic Act*, § 916(a)(2)(b)). The interaction of these complex provisions related to federal preemption of state law has been the subject of challenges by the tobacco industry to state and local laws. Thus far, courts have upheld certain local ordinances restricting the sale of flavored tobacco products (*National Association of Tobacco Outlets, Inc. v. City of Providence* 2013; *U.S. Smokeless Tobacco Manufacturing Co. v. City of New York* 2013).

Legal Basis for Regulating E-Cigarettes as Tobacco Products

In the United States, e-cigarettes can be regulated either as products marketed for therapeutic purposes or as tobacco products. Since the advent of e-cigarettes in the United States around 2007, manufacturers have had the option to apply to FDA’s Center for Drug Evaluation and Research (CDER) or Center for Devices and Radiological Health (CDRH) for approval to market e-cigarettes for therapeutic purposes; as of August 2016, no e-cigarette manufacturers have received approval through this avenue.

In 2008 and early 2009, FDA detained multiple shipments of e-cigarettes from overseas manufacturers and denied them entry into the United States on the grounds that e-cigarettes were unapproved drug-device combination products (FDA 2011). Sottera, Inc., which now does business as NJOY, challenged that determination (*Smoking Everywhere, Inc. and Sottera, Inc., d/b/a NJOY v. U.S. Food and Drug Administration, et al.* 2010; Bloomberg Business 2015). Between the filing of the lawsuit and a decision on the motion for preliminary injunction, Congress passed the Tobacco Control Act and the President signed it into law. The Tobacco Control Act defines the term “tobacco product,” in part, as any product, including component parts or accessories, “made or derived from tobacco” that is not a “drug,” “device,” or “combination product” as defined by the *Federal Food, Drug, and Cosmetic Act* (21 U.S.C. 321(rr)) (*Family Smoking Prevention and Tobacco Control Act* 2009, § 101(a)). The District Court subsequently granted a preliminary injunction relying on the Supreme Court’s decision in *Brown and Williamson* (1996) and the recently enacted Tobacco Control Act. FDA appealed the decision and the U.S. Court of Appeals for the D.C. Circuit held that e-cigarettes and, therefore, other products “made or derived from tobacco” are not drug/device combinations unless they are marketed for therapeutic purposes, but can be regulated by FDA as tobacco products under the Tobacco Control Act (*Sottera, Inc. v. Food & Drug Administration* 2010).

On September 25, 2015, FDA proposed regulations to describe the circumstances in which a product made or derived from tobacco that is intended for human consumption will

be subject to regulation as a drug, device, or a combination product. The comment period for this proposed regulation closed on November 24, 2015.

Most e-cigarettes marketed and sold in the United States today contain nicotine made or derived from tobacco. Although some e-cigarettes claim that they contain nicotine not derived from tobacco, or that they contain no nicotine at all (Lempert et al. 2016), there may be reason to doubt some of these claims. Currently, synthetic nicotine and nicotine derived from genetically modified, nontobacco plants are cost-prohibitive for e-cigarette manufacturers, although technological advances could eventually increase the cost-effectiveness of using nicotine that was not derived from tobacco (Lempert et al. 2016). The health effects of passive exposure to e-cigarettes with no nicotine, as well as their actual use and the extent of exposure to these products, have just begun to be studied (Hall et al. 2014; Marini et al. 2014; Schweitzer et al. 2015) and some states and localities are taking steps to regulate e-cigarettes that do not contain nicotine or tobacco (Lempert et al. 2016).

Deeming Rule

The Tobacco Control Act added a new chapter to the *Federal Food, Drug, and Cosmetic Act*, which provides FDA with authority over tobacco products. The new chapter applied immediately to all cigarettes, cigarette tobacco, roll-your-own tobacco, and smokeless tobacco; and the law included “any other tobacco products that the Secretary of Health and Human Services by regulation deems to be subject to this chapter” (*Federal Food, Drug, and Cosmetic Act*, §901 (b)). Therefore, to regulate e-cigarettes as tobacco products, FDA was required to undertake a rulemaking process to extend its regulatory authority to include e-cigarettes.

Consequently, in May 2016, through its Center for Tobacco Products (CTP), FDA issued a rule—often referred to as the “deeming rule”—to extend its authority over all products meeting the definition of a tobacco product, except accessories of the newly deemed products. This rule extended FDA’s tobacco product authorities to include e-cigarettes and their components and parts (e.g., nicotine cartridges), but also to such products as cigars, pipe tobacco, nicotine gels, waterpipe/hookah tobacco, and dissolvables not already regulated as smokeless tobacco products (*Federal Register* 2016). This regulation is currently under litigation. The deeming rule subjects e-cigarettes to Tobacco Control Act provisions, including:

- Prohibitions on adulterated and misbranded products;
- Required disclosure of existing health information, including lists of ingredients and documents on health effects;
- Required registration of manufacturers;
- Required disclosure of a list of all tobacco products, including information related to labeling and advertising;
- Premarket review of new tobacco products (i.e., those not on the market on February 15, 2007);
- Restrictions on products marketed with claims about modified risk.

In addition to the aforementioned Tobacco Control Act provisions applicable to all deemed tobacco products, the Tobacco Control Act grants FDA authority to undertake a

broad range of other actions on specific classes of products. In its deeming rule, FDA included the following additional actions for tobacco products, including e-cigarettes:

- Minimum age restrictions to prevent sales to minors;
- Requirements to include a nicotine warning; and
- Prohibitions on vending machine sales, unless in a facility that never admits youth.

Future Regulatory Options

E-cigarette manufacturers have the option to apply to FDA to authorize the marketing of their products or to be able to manufacture and sell tobacco products marketed with modified-risk claims, in addition to the existing option to apply to FDA's CDER or CDRH for approval to market their products for therapeutic purposes. FDA also has authority to undertake a number of actions if the Secretary of USDHHS finds such actions to be appropriate for the protection of public health, including:

- Product standards, including restrictions on flavors;
- Restrictions on promotion, marketing, and advertising, and prohibitions on brand-name sponsorship of events;
- Minimum package sizes;
- Prohibitions on self-service displays;
- Child-resistant packaging and the inclusion of health warnings; and
- Regulation of nicotine levels in products.

Despite this broad authority, FDA is prohibited from certain regulatory actions, even if those actions may be appropriate for the protection of public health. Specifically, FDA generally cannot restrict tobacco use in public places, levy taxes on tobacco products, prohibit sales by a specific category of retail outlet (e.g., pharmacies), completely eliminate nicotine in tobacco products, require prescriptions for tobacco products unless it is marketed for therapeutic purposes, or establish a federal minimum age of sale for tobacco products above 18 years of age. Thus, even if FDA fully exercises all of its existing authority over e-cigarettes, regulation will still need to be complemented at the state and local levels, including efforts previously shown to be effective for conventional tobacco products, such as comprehensive smokefree laws at the state and local levels, pricing strategies, raising the minimum age of sales to minors to 21, and high-impact countermarketing campaigns. In the current context of rising rates of use by youth, localities and states can also implement policies and programs that minimize the individual- and population-level harms of e-cigarettes (see Chapter 5).

Summary

This chapter presents the major conclusions of this Surgeon General's report and the conclusions of each chapter. E-cigarettes are presented within their historical context, with an overview of the components of these devices and the types of products. In 2016, FDA announced its final rule to regulate e-cigarettes under the *Family Smoking Prevention and*

Tobacco Control Act. The chapter outlines options for the regulation of e-cigarettes, particularly as they relate to youth and young adults, based on successful smoking policies. The need to protect youth and young adults from initiating or continuing the use of nicotine-containing products forms a strong basis for the need to regulate e-cigarettes at the local, state, and national levels in the future.

SECTION 2. PATTERNS OF E-CIGARETTE USE AMONG U.S. YOUTH AND YOUNG ADULTS

Introduction

This chapter documents patterns and trends in awareness of electronic cigarettes (e-cigarettes), their use, and perceptions about these devices among youth and young adults in the United States. Both the awareness of e-cigarettes and levels of their use have increased rapidly throughout the U.S. population. Understanding young people’s patterns of e-cigarette

use is essential to determining the scope of potential benefits or harms that these products may have from a public health perspective. This chapter summarizes the patterns of use of e-cigarettes, identifies subgroups at higher risk for using them, highlights the ways in which e-cigarettes are used with other tobacco products, and identifies correlates of e-cigarette use, including knowledge, attitudes, beliefs, and sociodemographic characteristics. In most cases, the term “e-cigarette(s)” is used, but when needed to accord with usage in the cited literature, the acronym “ENDS” (electronic nicotine delivery systems) is employed.

Sources of Data

Data summarized in this chapter come from nationally representative datasets that were federally funded and peer-reviewed literature of subnational and international surveillance studies of e-cigarette use that were mostly cross-sectional in design. Appendix 2.1. and Table A2.1-1 in that appendix¹ describe all the years of data available for these data sources, but only selected years are used for this report. For youth, this report relies on data from the National Youth Tobacco Survey (NYTS) and the Monitoring the Future Study (MTF), as measures of e-cigarette use were available for at least two or more time points. For this reason, the report also relies on data from the National Adult Tobacco Survey (NATS) for young adults. More recently, the Youth Risk Behavior Surveillance System and other surveys from the National Center for Health Statistics have added measures of e-cigarette use to their surveys, but only one data point was available at the time this report was prepared. Only five longitudinal studies were available on this topic at the time this report was prepared (Leventhal et al. 2015; Primack et al. 2015; Barrington-Trimis et al. 2016; Unger et al. 2016; Wills et al. 2016). Because e-cigarettes only became prevalent in the tobacco product marketplace in recent years, minimal data are available on their use before 2011. Given the paucity of surveillance information on e-cigarettes and the low prevalence of their use in the early years of their availability in the United States, peer-reviewed studies with smaller subnational samples are used in this chapter to complement national surveillance data. Surveillance of e-cigarette use presents a unique set of challenges, given the emerging and dynamic market specific to these products (see Chapter 4 for more on the latter topic). Appendix 2.1 and Tables A2.2-1 and A2.2-2 in Appendix 2.2 summarize the key terms and measures used in this chapter.

Other Literature

This chapter also summarizes findings from peer-reviewed literature on e-cigarettes that were identified through a systematic review of studies of these products from the United States and abroad. A literature search was conducted in April 2015 (Glasser et al. 2015) using the National Library of Medicine’s PubMed database and the following keywords: “e-cigarette*” OR “electronic cigarette” OR “electronic cigarettes” OR “electronic nicotine delivery” OR “vape” OR “vaping.” Articles were excluded from this review for any of five reasons: (1) the article was not available in English; (2) the article was not relevant to e-cigarettes; (3) the study included nonhuman subjects; (4) the study did not include original data; or (5) the study did not include findings specific to adolescents or young adults. More details about this review’s methodology are available in Glasser and colleagues’ (2015)

¹ All appendixes and appendix tables that are cross-referenced in this chapter are available only online at <http://www.surgeongeneral.gov/library/reports/>.

report. The search was subsequently updated in November 2015, January 2016, and March 2016 during continued development of the report. For consistency, the same search strategy and databases were employed at all times. Studies on patterns of e-cigarette use behaviors for both youth and young adults are reviewed in the text and tables that follow. All other studies not explicitly described in the text are summarized in Appendix 2.3 and Tables A2.3-1 through A2.3-3.

Current Prevalence

Ever Use

According to the 2015 National Youth Tobacco Survey (NYTS), an estimated 27.1% of U.S. adolescents, representing approximately 7,260,500 persons, had ever tried e-cigarettes (Centers for Disease Control and Prevention [CDC], unpublished data [NYTS 2015]). This included 13.5% of middle school students and 37.7% of high school students (Tables 2.1a and 2.1b). Among middle school students, use was comparable between boys and girls, but it was higher among Hispanics compared with other racial/ethnic groups (Table 2.1a). For high school students, use was also comparable between boys and girls, but higher among both White and Hispanic youth compared with Black youth (Table 2.1b). According to data from the 2015 Youth Risk Behavior Survey (YRBS), a larger percentage of high school students (44.9%) had ever used e-cigarettes (Kann et al. 2016), while the Monitoring the Future (MTF) survey does not collect data on ever use of e-cigarettes (Johnston et al. 2016).

Past-30-Day Use

According to the 2015 NYTS, an estimated 620,000 middle school students and 2,390,000 high school students had used e-cigarettes at least once in the past 30 days (CDC 2016). This was an increase from the 2014 NYTS, which reported 450,000 middle school students and 2,010,000 high school students had used e-cigarettes in the past 30 days (CDC 2015c). Levels of past-30-day use were 5.3% for middle school students and 16% for high school students in 2015 (Tables 2.2a and 2.2b), compared with 3.9% for middle school students and 13.4% for high school students in 2014. Sociodemographic differences in past-30-day use for middle and high school students had the same patterns as those for ever use (Tables 2.2a and 2.2b). In 2015, according to the YRBS, 24.1% of high school students had used e-cigarettes at least once in the past 30 days (Kann et al. 2016). The 2015 MTF shows past-30-day prevalence of e-cigarette use among adolescents was 9.5% among 8th graders, 14% among 10th graders, and 16% among 12th graders (Johnston et al. 2016). Notably, data from NYTS, YRBS, and MTF show that in 2014 exclusive past-30-day use of e-cigarettes exceeded exclusive past-30-day use of conventional cigarettes for the first time since these types of data were collected (University of Michigan 2014; CDC 2015c).

Frequency of Use

Among middle school students, according to the 2015 NYTS, 5.3% were current users of e-cigarettes, and 0.6% used e-cigarettes frequently (defined as using an e-cigarette 20 or more days in the past 30 days preceding the survey) (Table 2.1a). Among high school students, these estimates were 15.5% and 2.5%, respectively (Table 2.1b). Due to smaller sample sizes, confidence intervals were too wide to determine sociodemographic differences in these measures. These estimates are consistent with a report by CDC (2015b).

A recent analysis of 2014 MTF data, specific to high school seniors, showed the frequency of e-cigarette use (defined as the number of days in the past 30 days a student used an e-cigarette) increases with ever cigarette smoking (Warner et al. 2016). Among high school seniors who used at least 1 e-cigarette in the past 30 days, the frequency of e-cigarette use was almost twice as high (10.2 days) among those who regularly smoke conventional cigarettes, compared to those who had never smoked a conventional cigarette (5.8 days). However, the frequency of e-cigarette use did not vary substantially among current cigarette smokers. Among high school seniors who used at least 1 e-cigarette in the past 30 days, the frequency of e-cigarette use averaged 8–10 days for “heavy cigarette smokers” (those who smoked more than a half pack of cigarettes per day), “light cigarette smokers” (those who smoked 1–5 cigarettes per day), and “very light cigarette smokers” (those who smoked fewer than 1 cigarette per day) (Warner et al. 2016).

Susceptibility to Use

Among those who had never used an e-cigarette, 32.1% of middle school students and 38.4% of high school students were susceptible to using e-cigarettes in the future. That is, these students did not have a firm resolve not to use e-cigarettes in the future. This is according to the 2015 NYTS (Tables 2.1a and 2.1b). No differences in susceptibility to use e-cigarettes were observed by gender or race/ethnicity for either middle school or high school students.

Trends in Prevalence

Ever Use

Overall, according to the NYTS, ever use of e-cigarettes among students in grades 6–12 increased from 3.3% in 2011, to 6.8% in 2012, to 8.1% in 2013, to 19.8% in 2014, and then to 27% in 2015 (Figure 2.1). As discussed in Appendix 2.2 (see NYTS Measures—Special Issues), measures of e-cigarette use were changed for the 2014 NYTS, as signaled by the dotted line in the figure. Research conducted using the New Jersey Youth Tobacco Survey suggests that the NYTS measures used in 2011–2013 may potentially underestimate use, compared with the 2014 measure (Delnevo et al. 2016). For the 2011–2015 period, use of e-cigarettes was higher in each year among high school students than among middle school students (Tables 2.3a and 2.3b).

Source: Centers for Disease Control and Prevention 2013a, 2014b; unpublished data (data: NYTS 2015).

Note: In 2014, modifications were made to the e-cigarette measure to enhance its accuracy, which may limit the comparability of this estimate to those collected in previous years. The dotted lines from 2013 to 2015 represent these differences.

^aIncludes those who responded “1 or more” to the following question: *During the last 30 days, on how many days did you use electronic cigarettes or e-cigarettes?*

Figure 2.1. Trends in ever e-cigarette use^a among U.S. middle and high school students; National Youth Tobacco Survey (NYTS) 2011–2015.

Middle School Students

Trends in ever use of e-cigarettes among U.S. middle school students are presented in Table 2.3a and Figure 2.1, using data from the 2011–2015 NYTS. The prevalence of ever use increased from 1.4% in 2011 to 2.7% in 2012, to 3.0% in 2013, to 10.1% in 2014, and then to 13.5% in 2015. The jump in prevalence between 2013 and 2014 may be an artifact of a change in how the use item was asked (see Appendix 2.2. Key Measures of Use). Nonetheless, prevalence of use would be expected to be minimal prior to 2011, suggesting that a considerable increase in use was still observed during this relatively short 4-year period. In 2015, among middle school students, an estimated 1,595,481 had ever tried e-cigarettes (CDC, unpublished data [NYTS 2015]). From 2011 to 2013, the prevalence of ever use did not differ significantly by gender or race/ethnicity. There remained no significant difference in ever use by gender in the 2014 or 2015 NYTS, but by 2014 and still in 2015, a greater percentage of Hispanic middle school students (18.6%) had tried e-cigarettes than White (12.2%) or Black (11.7%) students or students of other races/ethnicities (11.9%) (Table 2.3a).

High School Students

Trends in ever use of e-cigarettes among U.S. high school students are presented in Tables 2.3b and Figure 2.1, using data from the 2011–2015 NYTS. The prevalence of ever use increased from 4.7% in 2011 to 10% in 2012, to 11.9% in 2013, to 27.3% in 2014, and then to 37.7% in 2015. In that year, an estimated 5,624,876 high school students had ever used e-cigarettes (CDC, unpublished data [NYTS 2015]). In 2011–2013, male high school students had a higher rate of ever use each year compared with female students, but in 2014 the genders did not differ significantly in their rates. From 2011 to 2015, White and Hispanic high school students were more likely each year to be ever users than were Black students: In 2015, these figures were 38% and 43%, respectively, for White and Hispanic students compared with 28.5% for Black students.

Middle School Students

Trends in past-30-day use of e-cigarettes among middle school students in the United States are presented in Table 2.2a and Figure 2.2, again using data from the 2011–2015 NYTS. The prevalence of such use in this population increased from 0.6% in 2011 to 1.1% in 2012 and 2013, to 3.9% in 2014, and then to 5.3% in 2015 (Table 2.2a) (CDC 2016). Between 2011 and 2015, there were no significant differences in prevalence by gender; unstable estimates (see notes to the table) precluded an examination of differences in past-30-day e-cigarette use by race/ethnicity for 2011–2013. In 2014, the prevalence of past-30-day use was higher among Hispanics (6.2%) than Whites (3.1%), a trend that was also seen in 2015 with 8.3% of Hispanics and 4.4% of Whites reporting past-30-day use. From 2011 to 2015, increases were seen among females (0.4% to 4.8%), males (0.7% to 5.9%), Whites (0.6% to 4.4%), Hispanics (0.6% to 8.3%), and Blacks (1.1% in 2012 to 4.1%) (Table 2.2a) (CDC 2013b; CDC 2015c; CDC 2016).

Past-30-Day Use

According to the NYTS, past-30-day use of e-cigarettes among students in grades 6–12 in the United States increased from 1.1% in 2011 to 2.1% in 2012, to 3.1% in 2013, to 9.3% in 2014, and then 11.3% in 2015 (CDC 2013b; Ambrose et al. 2014; Lippert 2015; CDC, unpublished data) (Figure 2.2). In 2015, approximately 3,038,000 middle and high school students were past-30-day users of e-cigarettes (CDC, unpublished data [NYTS 2015]). Across all years, past-30-day use of e-cigarettes was higher among high school students than middle school students (Figure 2.2; Tables 2.2a and 2.2b). In the MTF, estimates were stable from 2014 to 2015; among 8th, 10th, and 12th graders, past-30-day use went from 8.7% to 9.5%, 16.2% to 14%, and 17.1% to 16.2%, respectively (University of Michigan, Institute for Social Research, unpublished data). Differences in trends in past-30-day use between the NYTS and MTF may be due to differences in age groups (e.g., the NYTS includes all grades in middle school and all grades in high schools) and the way in which these measures were asked on the instruments (see Table A2.2-1 in Appendix 2.2).

Source: Centers for Disease Control and Prevention 2013a, 2014b; unpublished data (data: NYTS 2015).
Note: In 2014, modifications were made to the e-cigarette measure to enhance its accuracy, which may limit the comparability of this estimate to those collected in previous years. The dotted lines from 2013 to 2015 represent these differences.

^bIncludes non-Hispanic Asian, non-Hispanic Native Hawaiian/Other Pacific Islander, and non-Hispanic American Indian/Alaska Native.

High School Students

Trends in past-30-day use of e-cigarettes among high school students are also presented in Table 2.2b and Figure 2.2, again using data from the 2011–2015 NYTS. The prevalence of such use in this population increased from 1.5% in 2011 to 2.8% in 2012, to 4.5% in 2013, to 13.4% in 2014, and then to 16% in 2015. From 2011 to 2013 and in 2015, males were significantly more likely each year to be past-30-day users than were females, but this difference was not significant in 2014 (Table 2.2b). From 2012 to 2015, Black high school students were less likely each year to be past-30-day users than were White or Hispanic high school students (Table 2.2b). During 2011–2015, large increases in past-30-day use were seen among females (0.7% to 12.8%), males (2.3% to 19%), Whites (1.8% to 17.2%), and Hispanics (1.3% to 16.4%) (Table 2.2b) (CDC 2013b, 2015c, 2016).

Young Adults

Current Prevalence

According to the 2013–2014 National Adult Tobacco Survey (NATS), among young U.S. adults aged 18–24 years, the prevalence of ever use and current use of e-cigarettes was 35.8% and 13.6%, respectively (Table 2.4a). These percentages were significantly higher than for the same measures among adults aged 25 years or over (16.4% and 5.7%, respectively) (Table 2.4b). Among young adults, ever and current use were both higher among males than females and for Whites than in other racial/ethnic groups (Table 2.4a). By educational attainment, among young adults, both ever and current use were lowest among those with a college degree (Table 2.4a). Among all young adults, 2% reported using e-cigarettes “every day”; while among current users in this age group, 15% reported this frequency (Table 2.4a). Use of e-cigarettes “every day” among older adults (≥ 25 years of age) was 1.3% overall and 22% among current users (Table 2.4b). Among young adults, sociodemographic differences in frequent use followed the same pattern as those for ever and current use (Table 2.4a).

Trends in Prevalence

According to the Styles (also known as HealthStyles or Summer Styles) survey, the prevalence of ever use of e-cigarettes among young adults aged 18–24 years was 6.9% in 2011, 4.1% in 2012, 7.8% in 2013, and 14.3% in 2014, a year that saw the addition of other products to this measure, including e-hookahs and e-pipes or e-cigars (Figure 2.3). Although the prevalence of ever use of e-cigarettes among young adults remained consistent from 2010 to 2013, it doubled from 2013 to 2014, presumably reflecting in part the addition of new products to the definition of e-cigarettes. In 2010, young adults (18–24 years) were more likely than older adults (25–44 and 45–64 years of age) to be ever users of e-cigarettes (King et al. 2015). In 2014, ever use of e-cigarettes or similar products was statistically equivalent between young adults (18–24 years old) at 14.3%, adults 25–44 years old at 15%, and adults 45–64 years old at 11.9% ($p > 0.05$) (CDC, unpublished data [Styles 2014]).

E-Cigarette Use and Use of Other Tobacco Products

Evidence from both national and regional studies suggests that e-cigarette use is strongly associated with other tobacco use, especially the use of combustible products (including conventional cigarettes, cigar products, and hookahs). However, many youth and young adults use e-cigarettes exclusively, too. Estimates from cross-sectional surveys such as the NYTS, MTF, and NATS are presented below for youth and young adults, followed by longitudinal studies that examine whether e-cigarette use precedes the use of other tobacco products (Leventhal et al. 2015; Primack et al. 2015; Barrington-Trimis et al. 2016; Unger et al. 2016; Wills et al. 2016).

Cross-Sectional Studies

Youth

Current Prevalence

Using data from the 2015 MTF survey, Figure 2.4 and Table 2.5 show past-30-day use of e-cigarettes and conventional cigarettes, including both exclusive and combined use of these products, among 8th-, 10th-, and 12th-grade students. In the 2015 MTF survey, 10.4% of 12th graders used e-cigarettes only, 5.3% used conventional cigarettes only, and 5.8% used both e-cigarettes and conventional cigarettes at least once in the past 30 days (Table 2.5) (MTF 2015a,b). For all grade levels, exclusive use of e-cigarettes was more prevalent (6.8%, 10.4%, and 10.4% of 8th, 10th, and 12th graders, respectively) than exclusive use of conventional cigarettes alone (1.4%, 2.2%, 5.3%, respectively). In the 8th and 10th grades, the combined or dual use of e-cigarettes and conventional cigarettes was also more prevalent than the use of conventional cigarettes alone (2.4% vs. 1.4%, and 3.5% vs. 2.2% for 8th and 10th graders, respectively); while in the 12th grade, the prevalence in the two categories was nearly identical (5.8% vs. 5.3%). As grade level increases, the ratio of any e-cigarette use to any conventional cigarette use decreases. Among 12th graders, dual use of these products was higher among boys than girls and among Whites than Blacks. In all grade levels, dual use was much higher among students who planned to attend fewer than 4 years of college compared to those who planned to attend 4 years of college. No other sociodemographic differences were observed among dual users (Table 2.5). For 10th and 12th graders, exclusive use of e-cigarettes was higher among boys than girls.

Tables 2.6a and 2.6b present data from the 2015 NYTS for middle and high school students. These data represent the percentages of tobacco users who were either lifetime or past-30-day users of e-cigarettes, by tobacco-use category (e.g., cigarettes only, other combustibles only). In these data, a correlation among the increasing levels of tobacco use, increasing complexity of poly-tobacco use, and e-cigarette use is apparent, with ever use and past-30-day use of e-cigarettes emerging as least prevalent among never tobacco users and most prevalent among the highest category of poly-tobacco users (conventional cigarettes plus other combustibles and noncombustibles) for both age groups. As an example, past-30-day e-cigarette use was rare (2.8%) among middle school students who did not use other

Notes: Questions on e-cigarette use were asked on four of six questionnaire forms. Data presented here are based on those four forms only.

^aParental education is an average score of mother's education and father's education.

tobacco products in that time period. However, using the standard of past-30-day-use for each category, the level of such use grew from 44.9% among those who had used cigarettes only; to 61.3% among those who had used cigarettes and other combustibles only; to 74.6% among those who had used cigarettes, other combustibles, and other noncombustibles only (Table 2.6a). These data are consistent with results from the 2013–2014 PATH study (n = 13,651 youth, 12–17 years old), which showed that 52.6% of past-30-day tobacco users also used e-cigarettes (Kasza et al. 2016).

Source: King et al. (2015) (data: HealthStyles 2010–2013); Centers for Disease Control and Prevention, unpublished data (data: HealthStyles 2014).

Note: In 2014, modifications were made to the e-cigarette measure to enhance its accuracy, which may limit the comparability of this estimate to those collected in previous years. The dotted lines from 2013 to 2014 represent these differences.

^aIncludes those who responded “electronic cigarettes or e-cigarettes” to the following question, “Have you ever tried any of the following products, even just one time? Electronic cigarettes or e-cigarettes, such as Ruyan or NJOY?”

Figure 2.3. Trends in ever e-cigarette use^a among U.S. adults by age group; Styles 2010–2014.

Source: University of Michigan, Institute for Social Research, unpublished data (data: MTF 2015).

Note: Questions on e-cigarette use were asked on four of six questionnaire forms. Data presented here are based on those four forms only.

Figure 2.4. Percentage of students in grades 8, 10, and 12 who used e-cigarettes and cigarettes in the past 30 days; Monitoring the Future (MTF) 2015.

According to the 2015 NYTS, among high school students, past-30-day use of e-cigarettes was also rare (3.4%) among never users of other tobacco products (Table 2.6b). In

contrast, 18.4% of ever smokers of cigarettes only; 36.3% of ever smokers of cigarettes and other combustible products only; and 55% of ever users of cigarettes, other combustibles, and other noncombustible products only had used e-cigarettes in the past 30 days. Although the survey found that just 7.3% of high school students were past-30-day exclusive users of e-cigarettes, many types of tobacco product users in the past 30 days were found to have used e-cigarettes in that period: 41.1% of cigarette-only smokers; 58.8% of cigarette smokers and smokers of other combustible tobacco products only; and 77% of cigarette, other combustible, and noncombustible product users only. Similarly, 27.4% of high school students who had not used tobacco products in the past 30 days had ever tried e-cigarettes, as had 80.8% of past-30-day cigarette-only smokers and 95.5% of those who had used cigarettes, other combustible, and other noncombustible tobacco products only (Table 2.6b).

Figure 2.5 presents data from the 2015 NYTS on the prevalence of past-30-day use of various tobacco products among middle and high school students. Although the overall level of tobacco use was lower in middle school, the patterns of poly-tobacco use were similar between the two groups, albeit with a larger proportion of poly-tobacco use in high school. An estimated 6.6% of high school students and 1.8% of middle school students were dual users of combustible tobacco products and e-cigarettes in 2015. Combined use of combustible tobacco, noncombustible tobacco, and e-cigarettes in the past 30 days was rare, with this pattern found for just 0.7% of middle school and 2.6% of high school students in 2015 (Figure 2.5). Longitudinal data are needed to follow individuals over time, ideally for several years, to more precisely examine both the trajectories into and out of cigarette and e-cigarette use and to determine if dual use is a steady state or a pathway-to-persistent-use-of-combustible-tobacco state (Cobb et al. 2015). The small number of such studies that currently exist are discussed below.

Trends in Prevalence

Tables 2.7a and 2.7b and Figures 2.6 and 2.7 present patterns of ever e-cigarette and poly-tobacco use over time, using the NYTS data from 2011 to 2015. Among both middle school and high school students, the exclusive use of combustible products declined over time, while both the exclusive use of e-cigarettes and the dual use of e-cigarettes with combustible products increased, especially from 2013 to 2015.

Middle School Students

In 2011, an estimated 21% of middle school students had ever used some form of tobacco in their lifetimes, compared to just 1.4% of middle school students who had ever used e-cigarettes (Table 2.7a). By 2015, 13.5% of middle school students had ever tried a tobacco product, while 3.5% had tried e-cigarettes. In that year, 4.5% of middle school students were ever users of e-cigarettes only; 6.2% were ever users of e-cigarettes and combustible products only; and 2.2% were ever users of combustible products, noncombustible products, and e-cigarettes. This means that 70% of middle school students who had ever used e-cigarettes had also experimented with a combustible tobacco product, although which came first is unknown. In 2015, for past-30-day use, exclusive e-cigarette use was 2.6% and exclusive combustible tobacco use was 1.2%. Also in 2015, the prevalence of past-30-day dual use of e-cigarettes and any other combustible or noncombustible product was similar to those estimates, at 2.7% (1.8% for e-cigarettes plus combustibles only, 0.2% for noncombustibles

and e-cigarettes only, and 0.7% for e-cigarettes plus combustibles and noncombustibles only). In 2015, ever use of cigarettes in combination with combustibles (6.2%) was equal to or higher than ever use of e-cigarettes only (4.5%) or combustibles only (4.4%) (Table 2.7a).

High School Students

In 2011, an estimated 47.2% of high school students had ever used other tobacco products in their lifetimes, compared to 4.7% who had ever used e-cigarettes (Table 2.7b). By 2015, 50.4% of high school students had ever tried a tobacco product, and 37.7% had ever used an e-cigarette. In 2015, 7.4% of high school students had ever used e-cigarettes exclusively; 20% were ever dual users of e-cigarettes and combustible products; 0.6% were

Source: Centers for Disease Control and Prevention, unpublished data (data: NYTS 2015).

Notes: CI = confidence interval; SE = standard error. *Cigarettes Only* includes those who reported trying cigarettes but not any other tobacco product. *Other combustibles* includes cigars, pipes, and hookah or bidis. *Noncombustibles* includes smokeless tobacco, dissolvables, or snus. *Other Combustibles Only* includes those who reported trying other combustibles but not cigarettes nor noncombustibles. *Noncombustibles Only* includes those who reported trying noncombustibles but not cigarettes nor other combustibles. *Cigarettes and Other Combustibles Only* includes those who reported trying cigarettes and other combustibles but not noncombustibles. *Cigarettes and Noncombustibles Only* includes those who reported trying cigarettes and noncombustibles but not other combustibles. *Other Combustibles and Noncombustibles Only* includes those who reported trying other combustibles and noncombustibles but not cigarettes.

Cigarettes, Other Combustibles, and Noncombustibles includes those who reported trying a product from each group.

^aIncludes those who responded “yes” to the following question, “Have you ever used an electronic cigarette or e-cigarette, even once or twice?”

^bIncludes those who responded “1 or more days” to the following question, “During the past 30 days, on how many days did you use electronic cigarettes or e-cigarettes?”

^cIncludes all respondents categorized into each group. It does not exclude those missing for e-cigarette status.

^dIncludes those who reported trying at least one of the following products (e-cigarettes not included in the definitions): *Cigarettes Only*; *Other Combustibles Only*; *Noncombustibles Only*; *Cigarettes and Other Combustibles Only*; *Cigarettes and Noncombustibles Only*; *Other Combustibles and Noncombustibles Only*; and *Cigarettes, Other Combustibles, and Noncombustibles*.

^eIncludes those who reported using at least one of the following products on 1 of the past 30 days (e-cigarettes were not included in the definitions): *Cigarettes Only*; *Other Combustibles Only*; *Noncombustibles Only*; *Cigarettes and Other Combustibles Only*; *Cigarettes and Noncombustibles Only*; *Other Combustibles and Noncombustibles Only*; and *Cigarettes, Other Combustibles, and Noncombustibles*.

ever dual users of noncombustible products and e-cigarettes only; and 9.1% were ever poly users of combustibles, noncombustibles, and e-cigarettes. However, the order of the use (i.e., which product came first) remains unknown. In 2015, 5.9% of high school students were exclusive past-30-day users of e-cigarettes; 6.6% were past-30-day dual users of e-cigarettes and combustible tobacco products; 0.7% were past-30-day dual users of e-cigarettes and noncombustible tobacco products only; and 2.6% were past-30-day poly users of e-cigarettes, combustible, and noncombustible tobacco products. Exclusive use of combustible products (6.8%) remained as prevalent as past-30-day dual use of e-cigarettes and combustible products (6.6%) among high school students (Table 2.7b).

Notes: For more information see Table 2.10a. In 2014, modifications were made to the e-cigarette measure to enhance its accuracy, which may limit the comparability of this estimate to those collected in previous years. The dotted lines from 2013 to 2015 represent these differences.

^aIncludes those who reported having tried at least one other tobacco product in their lives.

^bIncludes exclusive use of only e-cigarettes. It does not include use of any other product. Ever e-cigarette use includes those who responded “electronic cigarettes or e-cigarettes, such as Ruyan or NJOY” to the following question: “Which of the following tobacco products have you ever tried, even just one time?”

^cIncludes exclusive use of only cigarettes, cigars, pipes, bidis, kreteks, and/or hookahs. It does not include use of noncombustible products or e-cigarettes. They were defined using the following questions: Conventional cigarettes: “Have you ever tried cigarette smoking, even one or two puffs?” and “During the past 30 days, on how many days did you smoke cigarettes?”; cigars: “Have you ever tried smoking cigars, cigarillos, or little cigars, such as Black and Milds, Swisher Sweets, Dutch Masters, White Owl, or Phillies Blunts, even one or two puffs?” and “During the past 30 days, on how many days did you smoke cigars, cigarillos, or little cigars?”; pipes: “Have you ever tried smoking tobacco in a pipe, even one or two puffs?” and “During the past 30 days, on how many days did you smoke tobacco in a pipe?”; and hookahs, kreteks, and bidis: “Which of the following tobacco products have you ever tried, even just one time? (CHOOSE ALL THAT APPLY)” and “During the past 30 days, which of the following products have you used on at least 1 day? (CHOOSE ALL THAT APPLY).”

Figure 2.6. (Continued).

^dIncludes exclusive use of only smokeless tobacco, snus, and/or dissolvable tobacco. It does not include use of combustible products or e-cigarettes. They were defined using the following questions: Smokeless tobacco: “Have you ever used chewing tobacco, snuff, or dip, such as Red Man, Levi Garrett, Beechnut, Skoal, Skoal Bandits, or Copenhagen, even just a small amount?” and “During the past 30 days, on how many days did you use chewing tobacco, snuff, or dip?”; and dissolvables and snus: “Which of the following tobacco products have you ever tried, even just one time? (CHOOSE ALL THAT APPLY)” and “During the past 30 days, which of the following products have you used on at least 1 day? (CHOOSE ALL THAT APPLY).”

Young Adults²

Current Prevalence

Using data from the 2013–2014 NATS, current exclusive and combined use of e-cigarettes and cigarettes are presented in Figure 2.8 and Table 2.8a for young adults (18–24 years old), and in Figure 2.8 and Table 2.8b for adults 25 years of age and older. For both age groups, exclusive use of regular cigarettes was the most prevalent pattern of behavior (9.6%, young adults; 13%, adults), followed by dual use of cigarettes and e-cigarettes (7.5%, young adults; 4.2%, adults), and exclusive use of e-cigarettes (6.1%, young adults; 1.6%, adults). Among young adults, combined use of the two products and exclusive use of e-cigarettes were both higher among males than females; combined use was higher among Whites than in Hispanics or Blacks; and both combined use of the two products and exclusive use of e-cigarettes were lowest among those with a college degree.

Longitudinal Studies

Understanding the role that e-cigarettes play in the initiation of tobacco product use, especially conventional cigarettes and other combustible tobacco products, such as cigars and hookahs, is extremely important for informing public health policy, planning, and practice. It is unclear what impact e-cigarette use will have on the overall toll of tobacco use on public health (Cobb et al. 2015). Some researchers and policymakers are concerned about the order in which the initiation of tobacco products takes place, positing that the use of e-cigarettes could increase the likelihood that adolescents and young adults who have never used any tobacco products, but initiate e-cigarettes, will become lifetime users of conventional cigarettes or other tobacco products in sufficiently large numbers, resulting in a net harm to public health (USDHHS 2012). Other researchers suggest that the order of product initiation for tobacco products is unimportant and that experimentation with a variety of substances may be a marker of a common vulnerability to tobacco, alcohol, marijuana, and other substance-use behaviors (Vanyukov et al. 2012). Regardless, both of these perspectives on the effect of e-cigarette use on youth and young adults require longitudinal data to understand how current behaviors may affect health outcomes.

Five longitudinal studies to date suggest that e-cigarette use among youth (Leventhal et al. 2015; Barrington-Trimis et al. 2016; Wills et al. 2016) and youth and young adults (Primack et al. 2015; Unger et al. 2016) might lead to initiation of the use of combustible tobacco products in the future. The first study to appear was by Leventhal and colleagues (2015). In this study, a cohort of 9th graders in Los Angeles, California, was followed up at both 6 and 12 months, into 10th grade. Those who at base-line had never used combustible tobacco, but were ever users of an e-cigarette, were more likely to use combustible tobacco products at both follow-up points (odds ratio [OR] = 4.27, 95% confidence interval [CI], 3.19–5.71). Product-specific analyses showed that e-cigarette use in 9th grade was associated with the use of cigars (OR = 4.85, 95% CI, 3.38–6.96), hookahs (OR = 3.25, 95% CI, 2.29–4.62), and cigarettes (OR = 2.65, 95% CI, 1.73–4.05) in 10th grade. It was also associated with the number of different combustible products used in 10th grade (OR = 4.26, 95% CI, 3.16–5.74) (all ORs presented here were averaged across the two time points). In these

² As opposed to the situation in youth, cigarettes are the most commonly used tobacco product among young adults. Therefore, this chapter does not assess co-use of e-cigarettes and other tobacco products among young adults.

analyses, Leventhal and colleagues (2015) adjusted for demographic characteristics (age, gender, race/ethnicity, highest parental education), social factors (peer smoking, parental smoking), and intrapersonal factors (depression, impulsivity, delinquent behaviors) linked with cigarette smoking in previous research.

Primack and colleagues (2015), in a national cohort study, followed youth and young adults, 16–26 years of age, for 1 year. At baseline, only 16 participants (2.3%) had ever used e-cigarettes. In adjusted models that included only those who did not use conventional cigarettes at base-line and adjusted for gender, age, race/ethnicity, maternal educational level, sensation seeking, parental cigarette smoking, and peer cigarette smoking, baseline e-cigarette use was independently associated with progression to cigarette smoking (OR = 8.3, 95% CI, 1.2–58.6) and susceptibility to cigarette smoking (OR = 8.5, 95% CI, 1.3–57.2). Susceptibility was defined as a lack of a firm commitment not to smoke using established measures of this construct (Evans et al. 1995; Pierce et al. 1996).

Wills and colleagues (2016) followed a cohort of 2,338 students in grades 9 and 10 in Hawaii for 1 year. At baseline, 31% of the sample had ever used an e-cigarette, and 15% had ever used a conventional cigarette. One year later, these increased to 38% and 21%, respectively. Of those who had not used either of these products at baseline, 10% initiated exclusive e-cigarette use 1 year later; 2% initiated exclusive conventional cigarette use; and 4% initiated use of both products. Students who had never smoked a conventional cigarette at baseline but had used an e-cigarette at baseline were three times more likely to smoke

conventional cigarettes 1 year later (adjusted OR = 2.87, $p < 0.001$). By comparison, among those who smoked conventional cigarettes at baseline, use of e-cigarettes at that same point in time was not related to any reduction in the use of conventional cigarettes 1 year later ($p > 0.05$). Moreover, students were more likely to transition from never use to dual use of both products 1 year later if they were older, Caucasian or Native Hawaiian (compared with Asian-American), more rebellious, and perceived e-cigarettes as healthier (adjusted OR = 2.05, 2.15, 3.10, 3.32, 2.59, respectively, all $p < 0.001$).

Barrington-Trimis and colleagues (2016) followed a cohort of 11th and 12th grade students in California for more than 1 year (median 15.6 months). In this cohort, at baseline, 146 were ever e-cigarette users and 152 were never e-cigarette users; none had ever smoked a cigarette. Among never e-cigarette users at baseline, 16 participants (10.5%) reported using cigarettes at follow-up; among ever e-cigarette users at baseline, 59 participants (40.4%) reported the same (OR = 6.17; 95% CI, 3.30–11.60). After adjusting for cigar, pipe, or hookah use at baseline, the relationship attenuated only somewhat (OR = 5.48; 95% CI, 2.69–11.20). When stratified by susceptibility to cigarette smoking at baseline (defined, like Primack and colleagues [2015], as the lack of a firm commitment not to smoke using established measures of this construct [Evans et al. 1995; Pierce et al. 1996]), the relationship was actually stronger among those who were not susceptible (OR = 9.69; 95% CI, 4.02–23.40) compared to those who were susceptible (OR = 2.12; 95% CI, 0.79–5.74). The latter relationship was not statistically significant. In additional analyses that were restricted to those who reported no use of any combustible tobacco product at baseline, e-cigarette users were more likely to initiate use of any combustible tobacco product at follow-up (OR = 4.98; 95% CI, 2.37–10.4), including the use of cigarettes (OR = 4.29; 95% CI, 1.84–10.0), hookahs (OR = 2.86; 95% CI, 1.21–6.78), cigars (OR = 4.39; 95% CI, 1.72–11.2), and pipes (OR = 8.21; 95% CI, 1.20–56.2). The models used by Barrington-Trimis and colleagues (2016) adjusted for a variety of demographic characteristics (grade, gender, race/ethnicity, highest parental education) and social factors (peer and parental smoking). Additionally, gender, race/ethnicity (Hispanic White, non-Hispanic White, other), grade (11th or 12th), and ever use of hookahs were tested as potential effect modifiers of these associations, but no evidence was found for the same.

Unger and colleagues (2016) followed a cohort of 1,332 Hispanic young adults in California who provided survey data in 2014 and 2015. At baseline, these participants were an average of 22.7 years old. E-cigarette use at baseline was significantly associated with cigarette smoking (OR = 3.32; 95% CI, 1.55–7.10, among non-cigarette smokers at baseline) and marijuana use (OR = 1.97; 95% CI, 1.01–3.86, among non-marijuana users at baseline) at follow-up. Among those who did not smoke cigarettes at baseline ($n = 1,056$), 42 reported past month e-cigarette use in 2014; 26% of those who smoked e-cigarettes at baseline became cigarette smokers in 2015, compared to 7% of those who did not smoke e-cigarettes. Further, among those who did not smoke marijuana at baseline ($n = 1,028$), 68 reported past month e-cigarette use in 2014; 24% of those who smoked e-cigarettes at baseline became marijuana smokers in 2015, compared to 12% of those who did not smoke e-cigarettes. Moreover, in this study, e-cigarette use at baseline was *not* associated with cessation of cigarette smoking (OR = 1.31; 95% CI, 0.73–2.36) or marijuana use (OR = 1.05; 95% CI, 0.54–2.01) at follow-up. Among those who did smoke cigarettes at baseline ($n = 276$), 76% reported past month e-cigarette use in 2014; and 63% of those who smoked e-cigarettes at baseline were still smoking cigarettes at follow-up, compared to 58% of those who did not smoke e-cigarettes.

Covariates in these regression models included age, gender, past month use of alcohol, and past month use of other tobacco products (hookah, cigars, little cigars, smokeless tobacco).

Despite the several strengths of these studies, including their longitudinal nature, they had weaknesses as well. Rigotti (2015) notes, for example, that the study by Leventhal and colleagues (2015) could not distinguish between those who merely began experimenting with a combustible product and those who became regular smokers at follow-up. The same could be said for the studies by Barrington-Trimis and colleagues (2016), Primack and colleagues (2015), and Wills and colleagues (2016). Similarly, the single exposure measure of the independent variable (i.e., any e-cigarette use) in these studies did not allow the authors to assess whether there was a dose–response relationship between the extent of prior e-cigarette use and subsequent use of combustible tobacco products. In addition, the studies by Primack and colleagues (2015) and Wills and colleagues (2016) did not assess prior use at baseline of other tobacco products, marijuana, or alcohol. Though it is not highlighted prominently in their article, Leventhal and colleagues (2015) showed a bidirectional relationship between e-cigarette use and other combustible tobacco product use in their study: Use of other combustible tobacco products at baseline was significantly associated with the onset of e-cigarette use in two follow-ups. This hypothesis was not tested by Barrington-Trimis and colleagues (2016), Wills and colleagues (2016), or Primack and colleagues (2015). However, at the 1-year follow-up, Wills and colleagues (2016) did consider other demographics, personality, and psychosocial predictors of exclusive e-cigarette use and dual use of conventional cigarettes and e-cigarettes.

Concerns about the samples for the two studies can be raised as well. The samples in the studies by Barrington-Trimis and colleagues (2016) and Leventhal and colleagues (2015) were limited to youth in California; the study by Primack and colleagues (2015) suffered from a small sample size, with only 16 e-cigarette users at baseline (Leventhal et al. 2015; Primack et al. 2015); and the study by Wills and colleagues (2016) was limited to 9th- and 10th-grade students in Hawaii. Additional studies are still needed in the future to further elucidate any causal relationship in either direction between the use of e-cigarettes and other types of tobacco products, such as combustibles.

E-Cigarette Use and Other Substance Use

Few studies have investigated the co-occurrence of e-cigarette use and other risk behaviors in adolescents and young adults. The available evidence suggests that e-cigarette use is associated not only with the use of other tobacco products, but also with alcohol and other substance use, such as marijuana. This is consistent with the common liability model for substance use and other risky behaviors (Vanyukov et al. 2012). Because nearly all currently available studies on this topic focus on regional, international, and at-risk samples, the conclusions from most studies cannot be generalized to the U.S. population as a whole, however.

In the only nationally representative study examining the associations between e-cigarettes, alcohol, and other drug use in young adults 18–24 years of age, the odds of alcohol use were nine times as high and the odds of everyday/some-day marijuana use were three-and-a-half times as high among past-30-day e-cigarette users as they were for those who had not used these products in that period (Cohn et al. 2015). Elsewhere, in a nonprobability sample of college students 17–25 years of age, 66% of current e-cigarette users and 67% of current dual users were heavy drinkers, defined as consuming at least once, five or more

drinks (men) or four or more drinks (women) in a single sitting during the course of 1 month (Littlefield et al. 2015). In another study, this one of college students in New York, past-30-day use of e-cigarettes was positively associated with current binge drinking and tobacco product use, and it was less common among those 20–23 years of age (versus those 18 years of age), females, non-Hispanic non-Whites (compared with non-Hispanic Whites), and those reporting better-than-average school performance (Saddleson et al. 2015).

Data from a longitudinal cohort study of children with alcoholic parents found that adolescents (both middle and late adolescence) who used cigarettes, marijuana, or alcohol were significantly more likely to have ever used e-cigarettes. Among those who had used marijuana, e-cigarette use was associated with greater use of marijuana during the previous 30 days (Lessard et al. 2014). In a cross-sectional pilot study of seventh-grade students in Southern California, ever use of e-cigarettes was 11%, compared to 6.8% for cigarettes, 38.1% for alcohol, and 39% for cigarettes or alcohol. In this study, 80% of ever users of e-cigarettes had used alcohol, and 42.2% had used conventional cigarettes (Pentz et al. 2015).

In a 2013 sample of students ($n = 2,002$) in two states in the southeastern United States, 53.4% of e-cigarette users also used marijuana (Berg et al. 2015). Elsewhere, in a sample of young adults (18–23 years of age) at colleges and universities that was taken in 2013 in upstate New York ($n = 1,437$), 54.2% of past-30-day marijuana users, 23.9% of past-30-day alcohol users, and 40.3% of past-30-day binge drinkers had ever used e-cigarettes (Saddleson et al. 2015). In Switzerland, among a sample of eighth graders, nearly 60% of regular e-cigarette users “had been drunk” at least once in the past 30 days (defined as an affirmative response to the question, “have you been drunk in the previous 30 days”), and 44.8% had used marijuana at least once during that period (Suris et al. 2015).

There are several limitations to these observational studies. For example, when considering the associations derived from these observational studies, the order of initiation of the products of interest cannot be inferred. In addition, some biases cannot be ruled out because of the nature of the samples, and patterns of associations may reflect an underlying common liability to use substances and take part in other risky behaviors. Some studies adjusted for risk taking, sensation seeking, and impulsivity, while others did not.

E-Cigarettes and Marijuana

Because of their design, e-cigarettes may facilitate drug use among youth and young adults, as these products can be used as a delivery system for cannabinoids and other illicit drugs (Giroud et al. 2015; Morean et al. 2015; Schauer et al. 2016). The aerosolization of cannabis is a relatively new technology used to deliver inhaled tetrahydrocannabinol (THC) and other cannabinoids while reducing the toxic byproducts of smoked cannabis, which are primarily caused by combustion (Abrams et al. 2007). Laboratory studies of prototype aerosolizers have demonstrated that they can provide a relatively effective mode of delivering THC, with plasma THC concentrations similar to those obtained from smoking a standard marijuana cigarette (Abrams et al. 2007; Giroud et al. 2015). In addition, thermal metered-dose cannabis inhalers have been developed for medical applications; their technology is similar to that of e-cigarettes (Eisenberg et al. 2014). While the first generation of cannabis aerosolizers was developed to aerosolize dry cannabis, the widespread availability of e-cigarettes and rapid advances in their technology have led to the development of liquid/oil forms of cannabis/THC that can be used with e-cigarettes in a fashion similar to that employed when they are filled with nicotine (Giroud et al. 2015). Articles explaining how to

acquire and use THC-containing liquid using e-cigarette technology are accessible on the Internet and are strongly suggestive of relatively widespread awareness and use (Gray 2013).

The actual prevalence of users of marijuana aerosolizers and their experiences remain unclear and understudied (Van Dam and Earleywine 2010; Malouff et al. 2014). In one of the few published studies on this issue specific to youth, Morean and colleagues (2015) found that, among high school students in Connecticut, vaporizing cannabis was common among ever e-cigarette users (18%), ever cannabis users (18.4%), and ever dual users (26.5%). This finding suggests a need for more specific surveillance measures that take into account the use of drugs other than nicotine in e-cigarettes.

Use of Flavored E-Cigarettes

The liquid that is vaporized in an e-cigarette is available to consumers in a wide variety of flavors, including tobacco, mint/menthol, and fruit flavors. Although characterizing “flavors” are prohibited in cigarettes (with the exception of menthol and tobacco) by the *Family Smoking Prevention and Tobacco Control Act of 2009*, this practice is not currently prohibited in other tobacco products, like e-cigarettes. Retail sales data suggest that the consumption of flavored e-cigarettes and tobacco products, such as flavored cigars, has increased in recent years (Delnevo et al. 2015; Giovenco et al. 2015), and recent studies show that youth and young adults may find these flavored products more appealing than their unflavored counterparts (Table 2.9) (Ambrose et al. 2015; Krishnan-Sarin et al. 2015; McDonald and Ling 2015).

Data on the use of flavored e-cigarettes among youth and young adults is presented in Table 2.9. In the 2015 NYTS, participants were asked about any current use of e-cigarettes that were “flavored to taste like menthol (mint), alcohol (wine, cognac), candy, fruit, chocolate, or other sweets” (CDC 2015a, 1066). Among middle and high school students who were past-30-day users of e-cigarettes, 44.6%, had used a flavored e-cigarette in that timeframe (CDC, unpublished data [NYTS 2015]); this included 42.6% of middle school students and 45.1% of high school students (Table 2.9) (CDC 2015a). The use of flavored e-cigarettes did not differ by gender and was lowest among Blacks (Table 2.9) (CDC 2015a). The use of flavored e-cigarettes was highest among young adults, according to the 2013–2014 NATS (Table 2.9): among those who reported using e-cigarettes every day or some days, 91.6% of young adults (18–24 years old) reported using an e-cigarette flavored to taste like menthol, mint, clover, spice, candy, fruit, chocolate, or other sweets. On the other hand, 66.6% of adults (≥ 25 years of age) who reported using e-cigarettes every day or some days had used flavored e-cigarettes. No gender differences were noted for young adults, but Blacks, as with middle and high school students, reported the lowest rate of using flavored e-cigarette products.

Data from the 2013–2014 wave of the PATH study revealed that a majority of adolescents who used e-cigarettes use flavors. Of those who had ever tried e-cigarettes, 81% used flavors the first time they tried an e-cigarette; of past-30-day users, 85.3% regularly used flavored e-cigarettes (Ambrose et al. 2015). Ambrose and colleagues (2015) also reported that 81.5% of respondents aged 12–17 reported that they used e-cigarettes because “they come in flavors I like.” Elsewhere, among 8th, 10th, and 12th graders in the 2015 MTF study, about 40% said that the primary reason they used e-cigarettes was “because they tasted good.” In contrast, about 10% said they used e-cigarettes to quit smoking conventional cigarettes (University of Michigan 2015). In the 2015 MTF study, about two-thirds of 8th-, 10th-, and

12th-grade students said that they used “just flavouring” in their vaporizer when they “last used” a vaporizer, while only 20% reported that they used nicotine (Miech et al. 2016). While the findings specific to nicotine are unexpected, it is important to note that these data are self-reported. It is questionable whether youth know what nicotine is, let alone whether it is contained in the e-cigarette products that they are using. Moreover, even if youth were accurately reporting nicotine strength according to the label on the package, a study by Buettner-Schmidt and colleagues (2016) found that more than half of the labels on assessed e-cigarette products did not accurately reflect actual nicotine content in the product. Therefore, further research on nicotine content using objective measures (e.g., retail sales data) is warranted. Both the PATH and MTF studies, however, reinforce that flavorings may play an important role in the initiation of e-cigarette use.

Table 2.9. Percentage of youth (middle and high school students), young adults (18–24 years of age), and adults (≥25 years of age) using tobacco products who reported using flavored e-cigarette products, by gender and race/ethnicity; National Youth Tobacco Survey (NYTS)^a and National Adult Tobacco Survey (NATS)^b

Note: CI = confidence interval; SE = standard error.

^aFlavored e-cigarette product use in NYTS was determined by the response to the question, “Which of the following tobacco products that you used in the past 30 days were flavored to taste like menthol (mint), alcohol (wine, cognac), candy, fruit, chocolate, or other sweets?” Participants could select from a list of options to designate the flavored tobacco product(s) they used. (Among those who reported any use of e-cigarettes in the preceding 30 days.) Those who selected e-cigarettes were coded as “yes” for flavored e-cigarettes. Those who did not select e-cigarettes were categorized as “no” for flavored e-cigarettes. Excludes 82 current e-cigarette users whose answers were missing for all flavored tobacco response options.

^bFlavored e-cigarette product use in NATS was determined by the response to the question, “Were any of the electronic cigarettes that you used in the past 30 days flavored to taste like menthol, mint, clover, spice, candy, fruit, chocolate, or other sweets?” (Among those who reported using e-cigarettes every day or some days.) Those who selected “yes” were categorized as “yes” for flavored e-cigarettes. Those who selected “no” were categorized as “no” for flavored e-cigarettes. Excludes five every-day or some-day users who reported not using any noncigarette tobacco product in the past 30 days.

^cSample size <50. No estimates had a relative SE >.40.

^dIncludes non-Hispanic Asian, non-Hispanic Native Hawaiian/Other Pacific Islander, and non-Hispanic American Indian/Alaska Native. For young adults and adults, this group also includes multiracial.

Other regional studies have reinforced the popularity of flavored e-cigarette use among youth. Table 2.10 summarizes these data on the use of flavored e-cigarettes among youth and young adults. Krishnan-Sarin and colleagues (2015), for example, found that sweet-flavored

e-cigarettes were popular among middle and high school students. In another study, which examined nonsmoking middle and high school students and college-aged adults in New Haven County, Connecticut, Kong and colleagues (2015) found that “appealing flavors” was the second most common reason cited for experimenting with e-cigarettes, and in a qualitative study of young adults living in New York City, flavors were identified as an attractive aspect of e-cigarettes (McDonald and Ling 2015). In a study examining nonsmoking teens and adult smokers, the e-cigarette flavors tested appealed more to adults than to teens; non-smoking teens demonstrated equally low levels of interest in tobacco, fruit, and candy flavors (Shiffman et al. 2015). It should be noted, however, that this study was funded by NJOY, an e-cigarette company and, therefore, may have suffered from commercial bias. Additional concerns about this study concerning selection bias, validity of the survey measures, and reliability of the findings have been raised (Glantz 2015).

Consumer Perceptions of E-Cigarettes

Perceived Harm of E-Cigarettes

In the general population of U.S. adults, e-cigarettes have been perceived to be generally less harmful (Pearson et al. 2012; Czoli et al. 2014; Gallus et al. 2014; Richardson et al. 2014; Berg et al. 2015; Pokhrel et al. 2015) and less addictive (Dockrell et al. 2013; Li et al. 2013; Brown et al. 2014; Farsalinos et al. 2015; Harrell et al. 2015; Hendricks et al. 2015; Kadimpati et al. 2015; Wackowski and Delnevo 2015) than conventional cigarettes. The perceived harm of e-cigarettes relative to conventional cigarettes was lowest among those who were current smokers, followed by former smokers and then nonsmokers (Pearson et al. 2012; Richardson et al. 2014). In a nationally representative sample of U.S. adults, young adults 18–34 years of age were more likely than their older counterparts to perceive e-cigarettes as being less harmful than conventional cigarettes (Tan and Bigman 2014).

Table 2.10. Summary of studies on e-cigarette flavors among youth and young adults

Study	Design/population	Measures	Outcomes/findings
Ambrose et al. (2015)	• Cross-sectional • Wave 1 of PATH study • Household-based, nationally representative survey of 13,651 youth 12–17 years of age	• For each product ever used, youth were asked if it was flavored to taste like menthol, mint, clove, spice, candy, fruit, chocolate, alcohol (such as wine or cognac), or other sweets	• 81% of e-cigarette ever users used a flavored product at first use • 85.3% of past-30-day e-cigarette users used a flavored product • 81.5% of past-30-day users cited “because they come in flavors I like” as a reason for using e-cigarettes
Berg et al. (2015)	• Cross-sectional • Recruitment through Facebook targeting of tobacco and marijuana users and nonusers • 2014 • 1,567 participants, 18–34 years of age, living in the United States	• E-cigarette use (ever tried, number of days in past 30 days) • Flavors used or of interest	• Most commonly used flavor was fruit flavors (67%), which was most commonly reported by never cigarette smokers. • Current smokers were most likely to report using tobacco flavors, but least likely to report using caramel, vanilla, chocolate, cream, or candy flavors.
CDC (2015a)	• Cross-sectional • 2014 NYTS data • Three-stage cluster sampling procedure • Nationally representative sample of 22,007 U.S. middle and high school students	• Participants were asked about any current use of tobacco products that were “flavored to taste like menthol (mint), alcohol (wine, cognac), candy, fruit, chocolate, or other sweets” • Participants could select from a list of options	• Among current e-cigarette users, 63.3% used a flavored product

Study	Design/population	Measures	Outcomes/findings
Kong et al. (2015)	• Cross-sectional • 18 focus groups, schoolwide survey • Recruitment by flyers and active recruitment sessions • Years sample drawn: 2012–2013 • New Haven County, Connecticut • Youth: Middle and high school students; focus group n = 127 (youth); survey n = 4,780 • Young adults: New Haven County, Connecticut, college students; focus group n = 127 (young adults); survey n = 625	• Why did you try an e-cigarette?	• 43.8% of e-cigarette ever users experimented with e-cigarettes for the availability of appealing flavors School-level differences: $\chi^2(2, N = 1,157) = 18.63$, $p \leq 0.001$ • Compared with college students, high school students were more likely to experiment with e-cigarettes because of flavors (47% vs. 32.8%): $\chi^2(1, N = 1,116) = 13.61$, $p \leq 0.001$
Krishnan-Sarin et al. (2015)	• Cross-sectional • School-based survey • Recruitment by selected district reference groups • Year sample drawn: 2013 • Youth: Connecticut middle (n = 1,166) and high school (n = 3,614) students • Young adults: n/a	• Which of the following flavors of e-cigarettes have you tried?	• Most e-cigarette ever users preferred sweet flavors: • Sweet flavors: 56.8% • Menthol: 8.7% • Combos: 7.7% • Tobacco: 3% • Other: 2.8% • Menthol and tobacco flavors used mostly by e-cigarette users who were also cigarette smokers. • Menthol preference: • 3.5% (never smokers) • 5.5% (ever smokers) • 18.6 (current smokers) • Tobacco preference: • 0.5% (never smokers) • 2.4% (ever smokers) • 7.1% (current smokers)
McDonald and Ling (2015)	• Focus groups and semistructured interviews • Recruitment from bars through screener surveys • Years sample drawn: 2012–2013 • Youth: n/a • Young adults: 87 young adults, 18–27 years of age, in the boroughs of Manhattan, Brooklyn, and Queens in New York City	• Attraction to flavors	• Flavors were an attractive e-cigarette characteristic
Shiffman et al. (2015)	• Cross-sectional • Participants drawn from online research panel • Year sample drawn: 2014 • Youth: Nonsmoking teenagers, 13–17 years of age • Young adults: n/a	• Interest in e-cigarettes paired with various flavor descriptors	• Nonsmoking teens' interest in e-cigarettes was very low • (mean = 0.41 ± 0.14 [SE] on 0–10 scale). • Teen interest did not vary by flavor ($p = .75$)
Ford et al. (2016)	• Cross-sectional in-home survey • Wave 7 of the Youth Tobacco Policy Survey (YTPS) • Random location quota sampling • 1,205 youth, 11–16 years of age, in the United Kingdom	• Awareness of e-cigarettes • E-cigarette use • E-cigarette flavor awareness • Perceptions of harm	• 12% had tried e-cigarettes • 2% were regular users (confined to adolescents who had also smoked tobacco) • 82% were aware of at least one promotional channel (82%) • 69% were aware that e-cigarettes came in different flavours • Brand awareness was low • E-cigarettes were perceived as harmful (mean = 3.54, SD = 1.19)
Vasiljevic et al. (2016)	• Randomized controlled trial • Participants exposed to advertisements of candy-like flavored e-cigarettes, non-flavoured e-cigarettes, or control • Youth: 598 English children, 11–16 years of age	• Appeal of using e-cigarettes • Appeal of e-cigarette ads • Interest in buying and trying e-cigarettes following ad exposure	• Exposure to e-cigarette ads did not seem to increase the appeal of tobacco smoking in children. • Exposure to flavoured e-cigarette ads (compared with non-flavoured ads) increased the appeal and interest in buying and trying e-cigarettes in children.

Note: NYTS = National Youth Tobacco Survey; PATH = Population Assessment of Tobacco and Health Study; SD = standard deviation; SE = standard error.

Common theories of health behavior, such as the Theory of Reasoned Action and the Health Belief Model, posit that perceptions of harm influence tobacco-use behavior, with lower perceived harm encouraging higher levels of experimentation and current tobacco use (Primack et al. 2008). Monitoring both absolute perceived harm and perceived harm relative to conventional cigarettes could be an indicator of later product adoption. Table 2.11 presents studies of the perceived harm of e-cigarettes among adolescents and young adults that are included in this chapter.

Youth

Table 2.12a presents NYTS data from middle school and high school students on the perceived harm of using e-cigarettes on some days but not every day. In 2015, 61.9% of these students, overall, believed that e-cigarettes caused “little or some harm” under such conditions; 14.5%, “no harm”; and 23.6%, “a lot of harm.” However, when these data are stratified by students’ history of e-cigarette use, important differences become clear. Notably, 34.2% of past-30-day e-cigarette users believed e-cigarettes cause “no harm,” compared with 22.4% of ever e-cigarette users and only 9.5% of never e-cigarette users. Conversely, 29.4% of never e-cigarette users believed that e-cigarettes cause “a lot of harm,” compared with 8.3% of ever e-cigarette users and 6.8% of past-30-day e-cigarette users. These important differences by e-cigarette use status, which suggest perceptions of no harm related to e-cigarette use, were consistent for both middle school students and high school students (Tables 2.12b and 2.12c).

Three studies that used data from the 2012 NYTS examined the correlates of U.S. adolescents’ opinions about the perceived harm of e-cigarettes relative to the harm of conventional cigarettes. Non-Hispanic Whites, students who lived with a smoker (Cardenas et al. 2015) or had a family member who used tobacco (Amrock et al. 2015), and past-30-day users of tobacco products other than cigarettes were more likely to believe that e-cigarettes were safer than conventional cigarettes (Amrock et al. 2015). Conversely, girls and students 17 years of age or older were more likely to believe that e-cigarettes were more harmful than regular cigarettes (Amrock et al. 2015). The perceived harm of e-cigarettes decreased with increasing levels of cigarette smoking, such that in 2012, 25% of adolescent never smokers, 41.3% of adolescent ever smokers, and 54.2% of adolescent past-30-day smokers believed that e-cigarettes were less harmful than cigarettes (Ambrose et al. 2014). Prior use of e-cigarettes was also associated with perceived harm of that product. Among students who had ever tried e-cigarettes in 2012, 71.8% believed that they were less harmful than cigarettes, 12.1% equally harmful, and 5% more harmful. These estimates were similar to those for students who had used e-cigarettes in the past 30 days (Amrock et al. 2015). In addition, susceptibility to cigarette smoking among never smokers was associated with perceptions of low harm for e-cigarettes (Ambrose et al. 2014).

Although not all studies reviewed in this section included “don’t know” as a response option for questions on the harms of e-cigarettes, those that did, found that a large number of students were unsure of the relative harmfulness of e-cigarettes compared to conventional cigarettes (Ambrose et al. 2014; Amrock et al. 2015). In fact, among U.S. adolescents responding to the 2012 NYTS, “don’t know” was the most common response (41.1–53.3%) across all the demographic subgroups examined (gender, age, and race/ethnicity) (Amrock et al. 2015). In this sample, more never smokers (57.4%) than ever smokers (37.5%) or past-30-day smokers (24%) had not heard of or did not know enough about e-cigarettes to make a

judgment of harm (Ambrose et al. 2014). Future studies will benefit from examining the effect of harm perception on the use of e-cigarettes and other tobacco-use behaviors among adolescents.

Young Adults

Table 2.12d presents data from the 2013–2014 NATS on beliefs about harm from e-cigarettes among young adults (18–24 years old). Just over half (53.8%) of young adults believed that e-cigarettes were “moderately harmful,” 26.8% believed they were “very harmful,” and 19.4% believed they caused “no harm.” Levels of belief in moderate harm were quite similar by type of e-cigarette use: 52.8% of never users, 56.8% of ever (but not current) users, and 53.6% of current users. Ever and current users were more likely than never users to report that e-cigarettes were “not at all harmful,” while never users were more likely than the other two groups to report that e-cigarettes were “very harmful.”

Published studies on perceived harm of e-cigarettes from regional samples, primarily of college and university students, are presented in Table 2.11. A large survey ($n = 4,444$) of college students in North Carolina conducted in 2009 found that, as with adolescents, perceived harm of e-cigarettes, compared with conventional cigarettes, was lower among college students who had ever used e-cigarettes (45%) than among those who had never used e-cigarettes (22%) (Sutfin et al. 2013). Just over half of the participants in this study who had never tried e-cigarettes, however, said that they did not know enough to judge the relative harm of e-cigarettes compared to conventional cigarettes. In this study and another study, lack of knowledge about the perceived harm of e-cigarettes relative to conventional cigarettes was associated with lower odds of using e-cigarettes (Sutfin et al. 2013; Choi and Forster 2014b). In the study by Choi and Forster (2014b), lower perceived harm of e-cigarettes and the belief at baseline that e-cigarettes can help people quit smoking were both associated at follow-up with a higher likelihood of having tried e-cigarettes.

Table 2.11. Summary of studies on perceptions of e-cigarette harm among youth and young adults

Study	Design/population	Measures	Outcomes/findings	Comments
Choi et al. (2012)	- Focus groups - Recruitment by (1) online advertisements, (2) flyers on one 4-year and two 2-year college campuses, (3) announcements in student life newsletter at a 2-year college, and (4) recruitment booth on a 2-year college campus - Year sample drawn: 2010 - Youth: n/a - Young adults: Individuals in Minneapolis-St. Paul, MN, enrolled in or who had graduated from 4-year colleges, or those who were enrolled in or had graduated from 2-year colleges, or those who had not enrolled in postsecondary education; $N = 66$	Perceived harmfulness relative to cigarettes	- No consensus among participants - Lack of information on ingredients, (2) health impact, and (3) mechanism used to vaporize nicotine - Some noted e-cigarettes to be as harmful as cigarettes (“all one product, in different forms”)	- Generalizability - Limited sample size

Table 2.11. (Continued)

Study	Design/population	Measures	Outcomes/findings	Comments
Adkison et al. (2013)	- Parallel prospective cohort - Telephone interview and web-based surveys - Probability sampling methods (random-digit dialing) - Years sample drawn: 2010–2011 (Wave 8), 2008–2009 (Wave 7, where available) - Youth: n/a - Young adults: current smokers, ≥18 years of age; N = 5,939 (Canada: n = 1,581; United States: n = 1,520; United Kingdom: n = 1,325; Australia: n = 1,513)	Are electronic cigarettes more harmful than, less harmful than, or equally harmful as regular cigarettes to one's health?	Not explicitly reported for young adults	- Inclusion of only current and former cigarette smokers - Limited set of questions
Faletau et al. (2013)	- Qualitative exploratory - Structured focus groups and individual interviews - Recruited from two low socioeconomic primary schools in East and South Auckland, New Zealand - Year sample drawn: 2011 - Youth: Maori, Tongan, Samoan, Cook Island, and Niuean children, 6–10 years of age; N = 20 - Young adults: n/a	Viewed tobacco cigarette and electronic cigarette videos	Still allows smokers to smoke, despite its function as a cessation aid	- Generalizability - Unknown if saturation was reached in children between focus groups - and individual interviews
Sutfin et al. (2013)	- Cross-sectional - Web-based survey (part of a randomized group trial) - Stratified random sample - Year sample drawn: 2009 - Youth: n/a - Young adults: undergraduate students attending eight universities in North Carolina; N = 4,857 (completers of e-cigarette question, n = 4,444).	- Compared with a regular cigarette, how harmful do you think e-cigarettes are? - Less harmful - As harmful - More harmful - Do not know	- Among the overall sample: 17% indicated “as harmful” 23% indicated “less harmful” 2% indicated “more harmful” 50% indicated “do not know” - Among ever e-cigarette users: 17% indicated “as harmful” 45% indicated “less harmful” 3% indicated “more harmful” 23% indicated “do not know” - Among never e-cigarette users: 16% indicated “as harmful” 22% indicated “less harmful” 2% indicated “more harmful”	- Low response rate - Generalizability - Inability to differentiate former smokers from experimenters - Cross-sectional analysis

Study	Design/population	Measures	Outcomes/findings	Comments
Sutfin et al. (2013)			51% indicated “do not know” - Ever e-cigarette use significantly associated with harm perceptions ($p < 0.001$)	
Ambrose et al. (2014)	- NYTS - Cross-sectional - School-based survey - Three-stage cluster sampling - Year sample drawn: 2012 - Youth: U.S. middle and high school students (grades 6–12); $N = 24,658$ - Young adults: n/a	Do you believe that electronic cigarettes or e-cigarettes, such as Ruyan or NJOY, are less harmful, equally harmful, or more harmful than regular cigarettes?	30.6% (CI, 29.3–31.9%) of respondents believed - e-cigarettes are less harmful than cigarettes: never smokers: 25% (CI, 23.9–26.2%); ever smokers: 41.3% (CI, 39.1–43.6%); current smokers: 54.2% (CI, 51.0–57.4%) - Female and Hispanics were less likely to perceive e-cigarettes as less harmful than cigarettes compared with males and Whites, across all smoking statuses - Current smokers that had ever used e-cigarettes were more than twice as likely to perceive e-cigarettes as less harmful, compared with smokers who had never used e-cigarettes (AOR = 2.48; CI, 1.87–3.29) - Never smokers who had ever used e-cigarettes were almost six times as likely to perceive e-cigarettes as less harmful, compared with - never smokers who had never used e-cigarettes (AOR = 5.88; CI, 3.07–11.25)	- Perceived graduated risk - Self-reported items - Social desirability bias - Generalizability
Czoli et al. (2014)	- Cross-sectional - Survey - Recruitment through online panel of commercial market research company - Year sample drawn: 2012 - Youth: Canadian youth recruited from online panel, 16–30 years of age; $n = 1,188$	- Is this product harmful to your health? - Have you ever experienced any side-effects or adverse outcome(s) while using e-cigarettes?	- Mean score for agreement with e-cigarettes as harmful to your health (higher score indicates greater agreement): - Among cigarette nonsmokers: 5.5 (e-cigarette nonuser) vs. 4.4 (e-cigarette ever user)	- Cross-sectional analysis - Generalizability

Table 2.11. (Continued)

Study	Design/population	Measures	Outcomes/findings	Comments
	Young adults: Canadian young adults recruited from same online panel (see above)		- Among former smokers: 5.2 (e-cigarette nonuser) vs. 3.6 (e-cigarette ever user) - Among current smokers: 2.6 (e-cigarette nonuser) vs. 3.5 (e-cigarette ever user)	
Gallus et al. (2014)	- Cross-sectional - In-person survey - Representative multistage sampling - Year sample drawn: 2013 - Youth: n/a - Young adults: Italians ≥ 15 years of age; N = 3,000	- Indicate your opinion (true/ false) concerning e-cigarettes on the following: (1) Are not harmful for health (2) Are less harmful than traditional cigarettes because they do not contain nicotine (3) Are less harmful because there is no tobacco combustion (4) Are less harmful because they contain only nicotine (5) Are more harmful than traditional cigarettes (6) Are an efficient tool to quit smoking (7) Allow smoking even where it is forbidden	Findings not explicitly reported for young adults	- Unstable estimates due to small sample of e-cigarette users - Unvalidated survey
Tan and Bigman (2014)	- Cross-sectional - Health Information National Trends Survey 4 Cycle 2 - Collected between October 2012 and January 2013 - U.S. adults ≥ 18 years of age - N = 3,630, 29.8% 18–34 years of age	- Compared to smoking cigarettes, would you say that electronic cigarettes are: - Much less harmful - Less harmful - Just as harmful - More harmful - Much more harmful - I've never heard of electronic cigarettes	Compared with younger respondents (18–34 years of age), older respondents had 38%–72% lower odds of believing that e-cigarettes are less harmful than regular cigarettes	—
Tucker et al. (2014)	- Cross-sectional - Paper-based survey - Probability-based sampling - Year sample drawn: not reported - Youth: n/a - Young adults: homeless young adults,	Rate whether they perceive e-cigarettes to be less harmful, more harmful, or just as harmful as smoking cigarettes	44.9% viewed e-cigarettes as less harmful than conventional cigarettes 26.6% viewed e-cigarettes as just as harmful as conventional cigarettes	Did not collect information on youth's attitudes about alternate tobacco products besides e-cigarettes

Study	Design/population	Measures	Outcomes/findings	Comments
	17–25 years of age; N = 292 (subset of lifetime e-cigarette users, n = 83)		3.7% viewed e-cigarettes as more harmful than conventional cigarettes 24.8% did not know the relative harm	Did not collect information on the conditions under which they used various products
Amrock et al. (2015)	- NYTS - Cross-sectional - School-based survey - Three-stage cluster sampling - Year sample drawn: 2012 - Youth: U.S. middle and high school - students (grades 6–12); N = 24,658 - Young adults: n/a	Do you believe that electronic cigarettes or e-cigarettes, such as Ruyan or NJOY, are less harmful, equally harmful, or more harmful than regular cigarettes?	34.2% (CI, 32.8–35.6%) of adolescents considered e-cigarettes to be less harmful than cigarettes - Females were less likely than males to perceive e-cigarettes as less harmful than cigarettes - Lifetime e-cigarette users were more likely than never users to report e-cigarettes as less harmful than cigarettes (71.8% vs. 31%) - Past-30-day e-cigarette users were more likely than nonrecent users to report e-cigarettes as less harmful than cigarettes (73.8% vs. 33.1%)	- Missingness - Perceived graduated risk - Self-reported items - Social desirability bias - Generalizability
Berg et al. (2015)	- Cross-sectional - Online-based survey - Recruitment by random selection - Year sample drawn: 2013 - Youth: n/a - Young adults: U.S. university students; n = 2,002	- How harmful to your health do you think electronic cigarettes are? - How addictive do you think electronic cigarettes are? - How socially acceptable among your peers do you think electronic cigarettes are?	- Respondents considered e-cigarettes among the least harmful (4.26 ± 1.95), addictive (4.29 ± 2.08), and socially acceptable (4.12 ± 2.03) of the products considered - Electronic cigarettes were among the most positively perceived products (11.56 ± 4.22) - Predictors of more favorable perceptions included: - Being male ($p = 0.03$) - Parental tobacco smoking ($p = 0.02$) - More friends who smoke cigarettes ($p < 0.001$) - More friends who use hookah ($p < 0.001$) - More friends who use electronic cigarettes ($p = 0.04$) - Recent cigarette smoking ($p < 0.001$).	- Generalizability - Responder bias - Cross-sectional analysis

Table 2.11. (Continued)

Study	Design/population	Measures	Outcomes/findings	Comments
Camenga et al. (2015)	• Focus groups • Purposive sampling • Years sample drawn: 2012–2013 • Youth: middle and high school students in Connecticut; n = 68 • Young adults: college students in Connecticut; n = 59	• Discuss the comparison between e-cigarettes and cigarettes.	• Compared with nonsmokers, college and high school smokers were more likely to believe the use of e-cigarettes could lead to a persistent “craving” that would prevent successful smoking cessation • Compared with nonsmokers, college and high school smokers were more likely to believe that e-cigarette use would maintain nicotine addiction	• Transferability • Generalizability • Limited definition of e-cigarettes
Cardenas et al. (2015)	• Cross-sectional • School-based survey • Three-stage cluster sampling • Year sample drawn: 2012 • Youth: U.S. middle and high school students; full sample size not reported; subsample of children who • never tried smoking cigarettes, n = 14,861 • Young adults: n/a	• Do you believe that electronic cigarettes or e-cigarettes, such as Ruyan or NJOY, are less harmful, equally harmful, or more harmful than regular cigarettes?	• Participants who lived with a smoker were more likely to report e-cigarettes are less harmful than regular cigarettes (16.2% vs. 24.8%) • E-cigarette users were more likely to believe e-cigarettes are less harmful than regular cigarettes (70.9% vs. 27.5%)	• No limitations reported
Chaffee et al. (2015)	• Cross-sectional • Year sample drawn: 2014 • Youth: male high school students • from San Francisco; n = 104	• Participants were asked to estimate the probability (0–100%) that specific health or social outcomes would happen to them as a result of e-cigarette use (e.g., heart attack, lung cancer, get into trouble, upset family, etc.)	• Ever use of electronic cigarettes was associated with lower perceived probabilities that unfavorable outcomes would happen	—
Lotrean (2015)	• Cross-sectional • 2013 • Students 19–24 years of age from Cluj-Napoca, Romania; n = 480	• Belief that e-cigarettes are less dangerous than cigarettes: agree, partially agree, disagree, partially disagree, don’t know	• 55.9% of the total sample agreed or partially agreed that e-cigarettes are less dangerous, 35.8% did not know, and 8.3% disagreed or partially disagreed • More smokers than nonsmokers or ex-smokers agreed or partially agreed that e-cigarettes are less dangerous (62.3% vs. 58.7% and 33.3%, respectively)	• Very small sample • Measures not clearly defined

Study	Design/population	Measures	Outcomes/findings	Comments
McDonald and Ling (2015)	- Focus groups and semistructured interviews - Recruitment from bars through screener surveys - Years sample drawn: 2012–2013 - Youth: n/a - Young adults: young adults in the boroughs of Manhattan, Brooklyn, and Queens in New York City, 18–27 years of age; N = 87	Perceived risks	- Little knowledge of the devices - Belief that e-cigarettes contain harmless “water vapor” rather than smoke - Belief that “water vapor” is less harmful or even “good” for users	No limitations reported
Roditis and Halpern-Felsher (2015)	- Focus groups - Recruitment from after-school programs in urban Northern California 2–6 participants in each group 24 adolescents: 9 female, 15 male	Perceived risks and benefits associated with conventional cigarettes versus e-cigarettes	- Little knowledge of risks of e-cigarette use - Belief that e-cigarettes have no nicotine	—
Cooper et al. (2016)	- Cross-sectional - Drawn from 2014 Texas Youth Tobacco Survey, a school-based survey - Youth: students in grades 6–12 from 27 counties in Texas; N = 13,602	“How dangerous do you think it is for a person your age to use electronic cigarettes?”	- Those in the e-cigarette-only group viewed conventional cigarettes as more harmful than did those in the dual user group - No differences in how harmful those in the e-cigarette-only group and the dual user group rated e-cigarettes - Those in the cigarette-only group rated e-cigarettes as more harmful than did those in the dual user group	—

Note: Studies in this table are sorted by year of publication and then alphabetically. AOR = adjusted odds ratio; CI = confidence interval; NYTS = National Youth Tobacco Survey.

Table 2.12a. Percentage of middle school and high school students who reported that using e-cigarettes on some days but not every day caused no harm, little/some harm, or a lot of harm^a, by e-cigarette smoking status; National Youth Tobacco Survey (NYTS) 2015

No harm			Little/some harm		A lot of harm

Source: Centers for Disease Control and Prevention, unpublished data (data: NATS 2013–2014).

Notes: CI = confidence interval. There were three young adults who were excluded because of missing responses for both ECIGEVER and ECIGNOW.

^aIncludes responses to the question, “How harmful do you think using e-cigarettes are to a person’s health?”

^bIncludes those who reported having never tried e-cigarettes or having never heard of them.

^cIncludes those who reported having heard of e-cigarettes and tried e-cigarettes but reported using them “not at all” at the time of the interview.

^dIncludes those who reported having heard of e-cigarettes, tried e-cigarettes, and using e-cigarettes some days, every day, or rarely at the time of the interview.

*Reasons for Use and Discontinuation***Reasons for Use**

Table 2.13 summarizes studies of reasons for using and discontinuing e-cigarettes. The most commonly cited reasons for use by adolescent and young adult e-cigarette users included curiosity (Schmidt et al. 2014; Biener and Hargraves 2015; Biener et al. 2015; Kong et al. 2015; McDonald and Ling 2015; Suris et al. 2015; Sutfin et al. 2015), flavorings/taste (Ambrose et al. 2015; University of Michigan 2015), use as a less harmful/less toxic alternative to conventional cigarettes (Peters et al. 2013; Tucker et al. 2014; Ambrose et al. 2015; Kong et al. 2015; McDonald and Ling 2015; Sutfin et al. 2015), and avoidance of indoor smoking restrictions or disturbing people with second-hand smoke from conventional cigarettes (Tucker et al. 2014; Ambrose et al. 2015; Kong et al. 2015; McDonald and Ling 2015; Suris et al. 2015; Sutfin et al. 2015). Other reasons youth and young adults reported trying or using e-cigarettes included affordability and lower cost than conventional cigarettes (Tucker et al. 2014; Ambrose et al. 2015); accessibility and convenience (Choi et al. 2012; Kong et al. 2015); social approval and/or offer from a family member or friend (Peters et al. 2013; Kong et al. 2015; Suris et al. 2015; Sutfin et al. 2015); perception that e-cigarettes are “cool,” “modern,” or “high-tech” (Choi et al. 2012; Kong et al. 2015); avoidance of smelling cigarette smoke (Peters et al. 2013; Tucker et al. 2014; Ambrose et al. 2015; Kong et al. 2015; Sutfin et al. 2015); ease of keeping hidden from parents/teachers (Peters et al. 2013; Kong et al. 2015); and weight control (Tucker et al. 2014). Young adults also perceived that e-cigarettes were more socially acceptable than smoking conventional cigarettes in public (Trumbo and Harper 2013).

Some youth and young adults also reported using e-cigarettes as an aid to reducing and/or quitting their use of conventional cigarettes (Li et al. 2013; Schmidt et al. 2014; Tucker et al. 2014; Suris et al. 2015; Sutfin et al. 2015; Bold et al. 2016). Data from the 2012 NYTS, however, suggest that while e-cigarette use among U.S. youth may be associated with intentions to smoke conventional cigarettes, it is not associated with intentions to quit conventional cigarette smoking (Park et al. 2016). This is further reinforced by a study of young adults from Switzerland, which found that after 15 months of follow-up, e-cigarette use was not associated with either cessation or reduction in the use of conventional cigarettes (Gmel et al. 2016). There is some evidence to suggest that curiosity was a stronger driver of an e-cigarette trial among young adults than smoking cessation, and that smoking cessation was a stronger driver of such a trial among older adults (Schmidt et al. 2014). Other evidence suggests that reasons for use were driven by tobacco-use status, with regular adolescent e-cigarette users much more likely than adolescents who had used e-cigarettes just once to give the reason for use as smoking cessation, smoking reduction, or avoidance of smoke-free air regulations (Suris et al. 2015). Nationwide, according to the 2015 MTF (University of Michigan 2015), “because they tasted good” was cited as a reason to use e-cigarettes among 40% of 8th-, 10th-, and 12th-grade users, versus just 10% who reported they used them in an attempt to quit smoking conventional cigarettes. In a New Zealand study, interest in using e-cigarettes to quit using conventional cigarettes was higher among young adults than older adults (Li et al. 2013). Finally, another study, this one conducted among high school, middle school, and college students in Connecticut in 2012–2013, found that although the students were aware that e-cigarettes could be used to aid in smoking cessation, they thought that few smokers had successfully used e-cigarettes to quit smoking (Camenga et al. 2015). However,

in an article published by this group (Bold et al. 2016), trying e-cigarettes to quit smoking was the most robust predictor of continued e-cigarette use 6 months later, using a multivariable model that included all reasons simultaneously, though this reason was only endorsed at baseline by 5.9% of youth. Low cost was the most robust predictor of more frequent use 6 months later, though only 10% of students endorsed this reason at baseline (Bold et al. 2016). Therefore, the reasons to experiment with e-cigarettes are likely different from the reasons to continue using them, over time.

No randomized controlled trials specific to the efficacy of using e-cigarettes for quitting conventional cigarette smoking for young adults have been conducted to date. Although use of e-cigarettes as a potential cessation device for conventional cigarette smoking among adults is important to examine (e.g., McRobbie et al. 2014; McNeill et al. 2015), none of this evidence is included here, as it does not directly discuss youth and young adults. Three observational studies specific to this issue, however, have been conducted among young adults to date. Data from a population-based cohort study of U.S. young adults in the Midwest suggest that e-cigarettes are not effective as a technique for quitting the use of conventional cigarettes. In that study, 11% of cigarette smokers who had used e-cigarettes in the past 30 days at baseline quit smoking at the 1-year follow-up, compared with 17% of cigarette smokers who had never used e-cigarettes (OR = 0.93, $p = 0.93$) (Choi and Forster 2014a). Another cohort study of Swiss young adult men concluded that there were no beneficial effects of vaping for conventional cigarette smoking cessation or smoking reduction (Gmel et al. 2016). In this study, e-cigarette users reported lower cigarette smoking cessation rates at follow-up among those who were occasional cigarette smokers at baseline (OR = 0.43; 95% CI, 0.19–0.96). No differences between e-cigarette users and nonusers were noted among those who were daily cigarette smokers at baseline (OR = 0.42; 95% CI, 0.15–1.18). No differential changes between e-cigarette users and nonusers in the number of conventional cigarettes smoked per week were noted at follow-up, either (Gmel et al. 2016). In a study by Unger and colleagues (2016), which focused on Hispanic young adults in California, e-cigarette use at baseline (2014) was *not* associated with cessation of cigarette smoking (OR = 1.31; 95% CI, 0.73–2.36) or marijuana use (OR = 1.05; 95% CI, 0.54–2.01) at follow-up (2015), though e-cigarette use at baseline did increase the likelihood of transitioning from nonuser to user of cigarettes (OR = 3.32; 95% CI, 1.55–7.10) and marijuana (OR = 1.97; 95% CI, 1.01–3.86) (Unger et al. 2016). Additional research is required to determine any potential efficacy of e-cigarette use for conventional cigarette smoking cessation in young adults.

Reason for Discontinuation

In the small number of published studies on reasons for discontinuation of e-cigarette use in young users, adolescent and young adult smokers have cited lack of satisfaction and e-cigarettes' poor taste and cost (Kong et al. 2015) as reasons for discontinuing. Additional reasons have included negative physical effects (e.g., feeling light-headed) (Kong et al. 2015) and loss of interest. In one study of young adults aged 18–35, former and never smokers of conventional cigarettes also cited the idea that e-cigarettes were “bad for their health” as a reason for discontinuation (Biener and Hargraves 2015; Biener et al. 2015).

Table 2.13. Summary of studies on reasons for use and discontinuation of e-cigarettes among youth and young adults

Study	Design/population	Measures	Outcomes/findings
Adkison et al. (2013)	- Parallel prospective cohort - Telephone interview and web-based surveys - Probability sampling methods (random-digit dialing) - Years sample drawn: 2010–2011 (Wave 8), 2008–2009 (Wave 7; where available) - Youth: n/a - Young adults: current smokers, ≥ 18 years of age; N = 5,939 (Canada, n = 1,581; U.S., n = 1,520; United Kingdom, n = 1,325; Australia, n = 1,513)	- Four questions were asked regarding reasons for use (yes/no): - Electronic cigarettes may not be as bad as cigarettes for your health - Easier to cut down on the number of cigarettes you smoke - Can smoke in places where smoking conventional cigarettes is prohibited - Might help you quit	Not explicitly reported for young adults
Choi et al. (2012)	- Focus groups - Recruitment by (1) online advertisements, (2) flyers on one 4-year and two 2-year college campuses, announcements in student life newsletter at a 2-year college, and recruitment booth on a 2-year college campus - Year sample drawn: 2010 - Youth: n/a - Young adults: Individuals in Minneapolis-St. Paul, MN, enrolled in or who had graduated from 4-year colleges, or those who were enrolled in or had graduated from 2-year colleges, or those who had not enrolled in postsecondary education; N = 66	Potential as quit aids	- Ineffective as quit aids because: - Contain nicotine - Potential to be addicted to e-cigarettes - Eliminate social interaction aspect - Potential to help quit smoking because: - Potential for gradual reduction in nicotine
Choi and Forster (2013)	- Population-based prospective cohort study - Interview - Cluster random sampling - Years sample drawn: 2010–2011 - Youth: n/a - Young adults: U.S. midwestern adults, 20–28 years of age; n = 2,624 (sample from Minnesota)	- Indicate your level of agreement: - E-cigarettes can help people quit smoking - E-cigarettes are less harmful than cigarettes - E-cigarettes are less addictive than cigarettes	44.5% agreed e-cigarettes can help quit smoking; associated with the following characteristics: - Not being non-Hispanic White (AOR = 0.60; CI, 0.44–0.84) - Enrolled/graduated from 2-year college (AOR = 1.47; CI, 1.09–1.98) - Current smoker (AOR = 1.35; CI, 1.05–1.73) - At least one close friend who smokes (AOR = 1.27; CI, 1.03–1.57) 52.9% agreed e-cigarettes are less harmful than cigarettes; associated with the following characteristics: - Not being non-Hispanic White (AOR = 0.73; CI, 0.53–0.99) - Male (AOR = 1.39; CI, 1.15–1.67) - Current smoker (AOR = 1.42; CI, 1.11–1.83)

Table 2.13. (Continued)

Study	Design/population	Measures	Outcomes/findings
Choi and Forster (2013)			• 26.4% agreed e-cigarettes are less addictive than cigarettes; associated with the following characteristics: • Current smoker (AOR = 1.51; CI, 1.15–1.99) • Former smoker (AOR = 1.64; CI, 1.19–2.25) • At least one close friend who smokes (AOR = 1.28; CI, 1.00–1.63)
Faletau et al. (2013)	• Qualitative exploratory • Structured focus groups and individual interviews • Recruited from two low socioeconomic primary schools in East and South Auckland, New Zealand • Year sample drawn: 2011 • Youth: Maori, Tongan, Samoan, Cook Island, and Niuean children, 6–10 years of age; N = 20 • Young adults: n/a	• Viewed tobacco cigarette and electronic cigarette videos	• Stops people from smoking • People won't die • Protects those around e-cigarette users from sickness
Li et al. (2013)	• Cross-sectional • Telephone-based survey • Random-digit-dial sampling • Years sample drawn: 2011–2012 • Youth: n/a • Young adults: current smokers and recent quitters, ≥18 years of age, in New Zealand; N = 840	• Indicate your level of agreement: 1. E-cigarettes are safer to use than tobacco cigarettes (n = 317) 2. E-cigarettes can help people quit smoking tobacco (n = 313)	• OR = 1.81 (.78–4.18) among participants 18–24 years of age for perceived safety of e-cigarettes compared with participants ≥45 years of age • OR = 0.50 (0.21–1.17) among participants 18–24 years of age for perceived efficacy of e-cigarettes compared with participants ≥45 years of age
Pepper et al. (2013)	• Cross-sectional • Web-based survey • Recruited through parents who were members of an online panel assembled by random-digit dialing and address-based sampling. • Year sample drawn: 2011 • Youth: U.S. males, 11–17 years of age; N = 228 • Young adults: n/a	• If one of your best friends were to offer you an e-cigarette, would you try it? • If one of your best friends were to offer you a flavored e-cigarette (chocolate, mint, apple, etc.), would you try it?	• Overall, 18% were willing to try an e-cigarette if offered by a best friend: – 13% willing to try a plain e-cigarette – 5% willing to try flavored e-cigarettes or both kinds • Willingness to try e-cigarettes by age: – 11–13: 11% – 14–16: 15% – 17–19: 29% • OR = 3.26 (CI, 1.27–8.35) among those 17–19 years of age for willingness to try an e-cigarette, compared with those 11–13 years of age • Willingness to try e-cigarettes by smoking status: – Nonsmoker: 13% – Smoker: 74% • OR = 18.67 (6.22–55.98) among smokers for willingness to try an e-cigarette, compared with nonsmokers

Study	Design/population	Measures	Outcomes/findings
Peters et al. (2013)	• Focus groups • Recruitment through large, diverse high school in southwestern United States • Year sample drawn: 2012 • Youth: U.S. teenage boys; N = 47 • Young adults: n/a	• Why do youth use electronic cigarettes? • What do your friends think about electronic cigarettes? • Why are electronic cigarettes so popular?	• Reported reasons for use among youth: • Expeditionary consumption and concealment: 40% • High school approval: 26% • Healthier than cigarettes: 19% • Odorless: 15% • Reported perceptions of friends: • High school approval: 49% • Healthier than cigarettes: 36% • Safe high: 15% • Reported reasons for popularity: • Accessibility: 43% • Healthier than cigarettes: 30% • Aesthetics: 23% • Don't know: 4%
Trumbo and Harper (2013)	• Cross-sectional • Web-based survey • Recruitment by offer of extra credit to students in a 100-level course • Year sample drawn: 2011 • Youth: n/a • Young adults: freshmen and sophomores in a 100-level mass media in society course; n = 244	• Indicate your level of agreement with relative advantage: 1. I think e-cigarettes are safer in terms of "secondhand" smoke compared to tobacco cigarettes 2. I think e-cigarettes are not as harmful to users as tobacco cigarettes • Indicate your level of agreement with compatibility: 1. I think e-cigarette users can easily make use of existing smoking areas 2. I believe using e-cigarettes would fit in well with the lifestyle of most smokers • Indicate your level of agreement with complexity: 1. I believe it will not be difficult for smoker to learn how to use e-cigarettes 2. Overall, e-cigarettes are no more complicated to use than ordinary tobacco cigarettes • Indicate your level of agreement with "trialability": 1. I think it will be easy for people to purchase e-cigarettes 2. Smokers could easily give e-cigarettes a try to see if they like them better than tobacco	• Mean score (SD) of innovation items: 36.0 (4.7)
Zhu et al. (2013)	• Population • Online-based surveys • National probability sample • Year sample drawn: 2012 • Youth: n/a • Young adults: U.S. adults, >18 years of age; N = 10,041	• Why did you use e-cigarettes (yes/no)? 1. Safer than cigarettes 2. Cheaper than cigarettes 3. Easy to use when I can't smoke 4. To try to quit smoking cigarettes 5. Just because	• Not explicitly reported for young adults

Table 2.13. (Continued)

Study	Design/population	Measures	Outcomes/findings
Choi and Forster (2014b)	- Population-based prospective cohort study - Survey - Cluster random sampling - Years sample drawn: 2011–2012 - Youth: n/a - Young adults: participants in Minnesota Adolescent Community Cohort; n = 1,379	- Indicate your level of agreement with the following: - Using e-cigarettes can help people quit smoking - Using e-cigarettes is less harmful to health of the user than smoking cigarettes - E-cigarettes are less addictive than cigarettes	10% agreed that e-cigarettes can help people quit smoking; associated with e-cigarette experimentation at follow-up (AOR = 1.98; CI, 1.29–3.04) 10.1% agreed that e-cigarettes are less harmful than cigarettes; associated with e-cigarette experimentation at follow-up (AOR = 2.34; CI, 1.49–3.69) 9.3% agreed that e-cigarettes are less addictive than cigarettes
Czoli et al. (2014)	- Cross-sectional - Survey - Recruitment through online panel of commercial market research company - Year sample drawn: 2012 - Youth: Canadian youth recruited from online panel, 16–30 years of age; n = 1,188 - Young adults: Canadian young adults recruited from same online panel	- Indicate your agreement with the following reasons for trying e-cigarettes: - In places where you can't smoke cigarettes - For times when you don't want to smoke around others - To help you cut back on the amount you smoke - To help you while you are trying to quit smoking - As a long-term replacement for cigarettes - As a cheaper alternative to cigarettes	- Reasons for trying e-cigarettes among current cigarette smokers: –To help cut back on the amount they smoked (77.7%) –As a long-term replacement for cigarettes (77.8%) –For the times when they don't want to smoke around others (78.8%) –To help them while they are trying to quit smoking (80.4%) –As a cheaper alternative to cigarettes (80.7%) –In places where they can't smoke cigarettes (80.9%)
Li et al. (2014)	- Cross-sectional - Telephone-based survey - Recruitment by telephone-based omnibus survey and quitline client database - Year sample drawn: 2013 - Youth: n/a - Young adults: current smokers and recent quitters, ≥18 years of age, in New Zealand; N = 267	- Indicate your level of agreement: - Electronic cigarettes are for people who want to stop smoking completely - Electronic cigarettes are for people who want to cut down on their smoking - Electronic cigarettes are for people who want to still smoke in restricted public places such as inside a cafe, restaurant, or pub	- OR = 1.99 (CI, 0.99–3.97) among those 18–34 years of age for agreeing that “electronic cigarettes are for people who want to stop smoking completely,” compared with individuals ≥35 years of age - OR = 0.72 (CI, 0.24–2.21) among those 18–34 years of age for agreeing that “electronic cigarettes are for people who want to cut down on their smoking,” compared with individuals ≥35 years of age - OR = 0.93 (0.47–1.85) among those 18–34 years of age for agreeing that “electronic cigarettes are for people who want to still smoke in restricted public places such as inside a cafe, restaurant or pub,” compared with individuals ≥35 years of age
Schmidt et al. (2014)	- Cross-sectional - Telephone-based survey - Random-digit-dial sampling - Year sample drawn: 2013 - Youth: n/a - Young adults: noninstitutionalized adults in Montana; n = 5,000	- Select all of the reasons you initiated use of e-cigarettes: - To quit smoking cigarettes - To reduce cigarette consumption - To try something new (curiosity)	- Among those 18–34 years of age, approximately 50% reported trying e-cigarettes to quit or reduce cigarette use - Among those 18–34 years of age, approximately 70% reported trying e-cigarettes to try something new (curiosity)

Study	Design/population	Measures	Outcomes/findings
		4. To not disturb other people with smoke 5. To smoke in a place where cigarette smoking is prohibited 6. To save money 7. E-cigarettes might be less harmful than cigarettes 8. E-cigarettes taste better 9. Other	
Tucker et al. (2014)	• Cross-sectional • Paper-based survey • Probability-based sampling • Year sample drawn: not reported • Youth: n/a • Young adults: homeless young adults, 17–25 years of age; N = 292 (subset of lifetime e-cigarette users, n = 83)	• 18-item measure of reasons for using e-cigarettes, rating each reason on a 4-point scale (1 = not at all true, 4 = very true)	• Most common reasons for use included: Not having to go outside to smoke cigarettes (38%) – To deal with situations or places where they cannot smoke (36%) – To avoid bothering other people with tobacco smoke (31%) – Less common to report using e-cigarettes was to quit smoking (17–18%)
Ambrose et al. (2015)	• Cross-sectional • Wave 1 of PATH study • Household-based, nationally representative survey • Youth: 12–17 years of age; n = 13,651 • Young adults: n/a	• Past 30-day e-cigarette users were asked to report reasons for product use, including “it comes in flavors I like”	• 81.5% of past-30-day users cited “because they come in flavors I like” as a reason for using e-cigarettes • Other common reasons for use were “they might be less harmful to me than cigarettes” (79.1%); “they might be less harmful to people around me than cigarettes” (78.1%); and “I can smoke/use them at times when or in places where smoking cigarettes isn’t allowed” (58.9%)
Biener et al. (2015)	• Cross-sectional • Population-based mail survey • Dual-frame sample • Youth: n/a • Young adults: 18–25 years of age; n = 4,740	• Reasons for trying: curiosity, use by friends, health risks relative to cigarettes, absence of smell, for use where smoking is prohibited, and to quit or cut down on smoking • Reasons for stopping e-cigarette use: health concerns, negative reactions to taste and feeling sick, inferiority to other forms of tobacco, expense, lack of availability, and social disapproval	• Most common reason cited was curiosity, with never smokers more likely to cite this (77.3%) than former or current cigarette smokers (59% and 61%)
Camenga et al. (2015)	• Focus groups • Purposive sampling • Years sample drawn: 2012–2013 • Youth: middle and high school students in Connecticut; n = 68 • Young adults: college students in Connecticut; n = 59	• Discuss your motivations to use e-cigarettes	• Maintain smoking actions while allowing individuals to use a “healthier” nicotine product • Maintain tactile sensations to help with conditioned-smoking cues • College students believed e-cigarettes to be healthier than cigarettes

Table 2.13. (Continued)

Study	Design/population	Measures	Outcomes/findings
Kong et al. (2015)	• Cross-sectional • Focus groups, schoolwide survey • Recruitment by flyers and active recruitment sessions • Years sample drawn: 2012–2013 • Youth: New Haven County, Connecticut, middle and high school students; focus group n = 127 (youth and young adults); survey n = 4,780 • Young adults: New Haven County, Connecticut, college students; focus group n = 127 (youth and young adults); survey n = 625	• Focus group: – Why do you think people your age would use e-cigarettes? • Survey: – Why did you try an e-cigarette? – If you tried an e-cigarette but stopped using it, why did you stop?	• Focus group responses: – Reasons for use: • Influence of family and friends • To be “cool” • Curiosity • Readily available • Flavors – Comparison to cigarettes: • Healthier • Less harsh • Cheaper • Smells better • More convenient • Can hide it • Use it indoors – Reasons for discontinuation: • Losing interest • Negative physical effects (e.g., light-headed) • Bad taste • High cost • Less satisfying than cigarettes • Survey responses: – Reasons for experimentation (among lifetime e-cigarette users): • Curiosity (54.4%) • Friends’ influence (31.6%) – Reasons for discontinuation: • Uncool (16.3%) • Health risks (12.1%)
Li et al. (2015)	• Cross-sectional • 2014 • Nationwide, in-home survey in New Zealand • Multistage, stratified, clustered, and random probability sampling method (oversampling of Maori and Pacific peoples) • Participants ≥15 years of age; n = 2,594: – Youth: 15–17 years of age, 3.8% of sample – Young adults: 18–24 years of age, 13.4% of sample	• Why did you try using an electronic cigarette? (Multiple responses allowed— wanted to quit smoking cigarettes completely/wanted to replace smoking cigarettes some of the time/wanted to smoke in places where cigarette smoking is not allowed/cheaper than tobacco cigarettes/ safer than tobacco cigarettes/curiosity/ recommendation/other)	• 57.1% of ever users cited curiosity as a reason for first trying, followed by 31.3% of ever users who cited wanting to quit smoking completely • Current e-cigarette users were more likely than noncurrent users to report wanting to quit smoking completely as a reason for using e-cigarettes
McDonald and Ling (2015)	• Focus groups and semistructured interviews • Recruitment from bars through screener surveys • Years sample drawn: 2012–2013 • Youth: n/a • Young adults: young adults in the boroughs of Manhattan, Brooklyn, and Queens in New York City, 18–27 years of age; N = 87	• Bodily sensations • Use in response to clean air laws	• Vapor described as “harsh” or “burning” • Discontinued use because believed it would cause one to smoke more • Discontinued use due to fear of nicotine hangover • Use to smoke in places where conventional smoking is not allowed

Study	Design/population	Measures	Outcomes/findings
Pokhrel et al. (2015)	• Cross-sectional • Web-based survey • Recruitment by flyers across three college campuses • Year sample drawn: 2013 • Youth: n/a • Young adults: U.S. students from a 4-year university and two 2-year • community colleges in Oahu, Hawaii; n = 307	• Fourteen items, scored on a scale of 1 (do not agree) to 7 (agree), address three main beliefs. E-cigarettes: – Are less harmful than cigarettes – Improve the health of current smokers – May be used to quit smoking	• Participants generally scored harm-reduction items higher • Among health benefit items, “e-cigarettes improve breathing and reduce coughing” received the highest average score: mean (SD) = 3.9 (1.6) • Among smoking-cessation items, “e-cigarettes are a good compromise for people trying to quit smoking” received the highest average score: mean (SD) = 4.6 (1.8) • Across all items, “e-cigarettes cut down on the harmful effects of secondhand smoke” was scored the highest: mean (SD) = 5.3 (1.7) • 69% of participants agreed with the above item
Suris (2015)	• Cross-sectional • Data drawn from spring 2014 wave of <i>ado @ internet.ch</i>, a longitudinal study on Internet use • Representative sample of students in French-speaking part of Switzerland • Sample of 621 students included never e-cigarette users (n = 353), experimenters (n = 120), and users (n = 148); mean age = 16.2 years	• Reason for having used e-cigarettes? – Curiosity – To smoke where it is forbidden – To reduce smoking – To do like my friends – To quit smoking – Other	• Experimenters were significantly more likely to have used e-cigarettes for curiosity while users were more likely to use them where it is forbidden to smoke (p<.01)
Sutfin (2015)	• Longitudinal cohort study • Data from the Smokeless Tobacco Use in College Students Study • College students from North Carolina and Virginia • Reasons for e-cigarette use were evaluated at Wave 6 of the study, n = 271	• Why did you try e-cigarettes? (check all that apply): – “I was curious about the product” – “It might be better for my health than smoking cigarettes” – “My friends use e-cigarettes” – “I can use it in places where cigarette smoking is not allowed” – “To help me quit smoking” – “To cut down on smoking” – “It doesn’t smell bad”	• The majority (91.6%) reported curiosity as a reason for trying e-cigarettes • More than 70% tried e-cigarettes because their friends used them • About 70% tried e-cigarettes because they believed them to be better for their health than cigarettes • Fifty percent cited, “It doesn’t smell bad,” and “I can use it where cigarette smoking is not allowed” • About 31% said that they used e-cigarettes to cut down on smoking • Twenty percent said that they tried e-cigarettes to help them quit smoking
University of Michigan (2015)	• Cross-sectional • Data from the Monitoring the Future Study	• “What have been the most important reasons for your using an electronic vaporizer, such as an e-cigarette?” – To help me quit regular cigarettes	• More than half of all students in 8th, 10th, and 12th grades reported that curiosity to see what they were like was a primary reason for use

Table 2.13. (Continued)

Study	Design/population	Measures	Outcomes/findings
University of Michigan (2015)	- School-based, self-administered, paper-and-pencil questionnaire with cross-sectional and longitudinal components - Students from 8th, 10th, and 12th grades - Weighted sample of students responding to the “reasons for use of electronic vaporizer” question: 603 (8th grade), 846 (10th grade), and 1,449 (12th grade)	- Because regular cigarette use is not permitted - To experiment to see what it’s like - To relax or relieve tension - To feel good or get high - Because it looks cool - To have a good time with my friends - Because of boredom—nothing else to do - Because it tastes good - Because I am “hooked”—I have to have it	- Forty percent said that they used e-cigarettes because they tasted good - About 10% said they used them in an attempt to quit smoking regular cigarettes
Berg (2016)	- Cross-sectional - Recruitment through Facebook targeting of tobacco and marijuana users and nonusers 2014 - Youth: n/a - Young adults: 18–34 years of age, living in the United States; N = 1,567	- Reasons for use: For what reasons do you/ might you use e-cigarettes? - Reasons for discontinued use: Why have you not used recently?	- Reasons for use among current e-cigarette users: “They might be less harmful than cigarettes” (77%) “They do not smell” (77%) “They help people quit smoking” (66%) “They cost less than other forms of tobacco” (62%) - Reasons for use among nonusers: “They might be less harmful than cigarettes” (41%) “They don’t smell” (34%) - Reasons for discontinuation: “Using other tobacco products instead” (43%) “They are too expensive” (35%) “I just don’t think about it” (31%)
Bold (2016)	- Longitudinal - Youth: New Haven County, Connecticut, middle and high school students 2013–2014 340 e-cigarette users at baseline	- Reasons for first trying e-cigarettes: - Curiosity - It is cool - Good flavors - Does not smell bad - Can hide it from adults - Low cost - My friends use it - My parents/family use it - Can use it anywhere - To quit smoking regular cigarettes - It is healthier than regular cigarettes	- In multivariable model, including all reasons simultaneously, trying e-cigarettes to quit smoking was the most robust predictor of current (i.e., past 30 days) e-cigarette use 6 months later; however, this reason was endorsed by very few youth (5.9%) - In multivariable model, including all reasons simultaneously, trying e-cigarettes because of low cost was the most robust predictor of more frequent e-cigarette use (i.e., more days/month) 6 months later; this reason was endorsed by few youth (10%)

Note: Studies in this table are sorted by year of publication and then alphabetically. AOR = adjusted odds ratio; OR = odds ratio; PATH = Population Assessment of Tobacco and Health Study; SD = standard deviation.

Evidence Summary

The most recent estimates available show that 13.5% of middle school students (2015), 37.7% of high school students (2015), and 35.8% of young adults (2013–2014) had ever used an e-cigarette (Tables 2.1a, 2.1b, and 2.4a). The most recent data also show that past-30-day use of e-cigarettes is higher among high school students (16% in 2015) and young adults (13.6% in 2013–2014) than among middle school students (5.3% in 2015) and adults (25 years of age and older) (5.7% in 2013–2014) (Tables 2.1b, 2.4a, and 2.4b). Among youth and young adults, rates of ever and past-30-day use of e-cigarettes have increased greatly since the earliest e-cigarette surveillance efforts began in 2011. The increases among adults 25 years of age and older, by comparison, have been less steep. Among middle school and high school students, both ever use and past-30-day use of e-cigarettes more than tripled from 2011 to 2015 (NYTS 2011–2015; Figures 2.1 and 2.2) (CDC 2013a; Ambrose et al. 2014; Lippert 2015), and among young adults (18–24 years of age), the prevalence of ever use more than doubled from 2013 to 2014 (Styles 2013–2014; Figure 2.3).

Among youth, past-30-day exclusive use of e-cigarettes among 8th, 10th, and 12 graders (6.8%, 10.4%, and 10.4%, respectively) was more common than exclusive use of conventional cigarettes (1.4%, 2.2%, and 5.3% in those grades) or dual use of e-cigarettes and conventional cigarettes (2.4%, 3.5%, and 5.8% in those grades) (Table 2.5; Figure 2.4). However, among young adults 18–24 years of age, the patterns were different. In that group, exclusive use of conventional cigarettes surpassed exclusive use of e-cigarettes and use of both types of products (Figure 2.8). For example, in 2013–2014, 9.6% of young adults smoked conventional cigarettes exclusively, 6.1% were current users of e-cigarettes, and 7.5% currently used both. The use of e-cigarettes and other tobacco products, such as combustibles, appeared to co-vary among youth and young adults (Figures 2.6, 2.7, and 2.8). Although five longitudinal studies suggest that e-cigarette use is related to the onset of other tobacco product and marijuana use among youth and young adults (Leventhal et al. 2015; Primack et al. 2015; Barrington-Trimis et al. 2016; Unger et al. 2016; Wills et al. 2016), some studies had limitations in their ability to distinguish experimental smokers from regular smokers at follow-up (Leventhal et al. 2015; Primack et al. 2015; Barrington-Trimis et al. 2016; Wills et al. 2016). Therefore, more studies are needed to elucidate the nature of any true causal relationship between e-cigarette use and combustible tobacco products. Investigation of whether e-cigarette use is related to other types of substance abuse (e.g., marijuana, alcohol) might help distinguish the extent to which e-cigarette use may precede or follow other forms of substance use in the context of the common liability/vulnerability model (Vanyukov et al. 2012).

Although use of other tobacco products has been the strongest correlate of ever and past-30-day e-cigarette use among youth and young adults, sociodemographic characteristics have also been associated with the use of these products. Across both ever use and past-30-day use measures, e-cigarette use has been more common among high school than middle school students, a pattern similar to trends seen in other categories of tobacco products (CDC 2015c). Among middle school students in 2014 and 2015 (CDC 2016), ever e-cigarette use was highest for Hispanics (Table 2.1a); among high school students, ever use was highest among Hispanics and Whites (Table 2.1b). No differences between boys and girls were observed among middle school students in 2015 (Tables 2.1a, 2.1b). However, in 2015 male high

school students were significantly more likely to report past-30-day use than their female counterparts (Table 2.2b) (CDC 2016). For young adults, ever and past-30-day use of e-cigarettes were significantly higher among males than females (Table 2.4a). Current e-cigarette use was significantly lower among Blacks than in other racial/ethnic groups (Table 2.4a). Ever and past-30-day e-cigarette use was also significantly lower among those with a college education. Continued research is warranted to monitor patterns of e-cigarette use across population groups by gender, age, race/ethnicity, and education, as well as by sociodemographic characteristics for which disparities in tobacco use have been noted. Availability of data on e-cigarette use among youth and young adults is currently limited, including geography (e.g., subnational data at the state or local levels), sexual orientation and gender identity (e.g., lesbian, gay, bisexual, transgender), and socioeco-nomic status (e.g., household income, poverty status) (CDC 2014a; Johnson et al. 2016).

Research on youth and young adults' e-cigarette-related knowledge, attitudes, and beliefs is still developing and remains relatively sparse. Perceived harm is the most developed area of research. Most youth and young adults believe e-cigarettes are "less harmful" than conventional cigarettes (Table 2.11). However, up to 50% of respondents in some of these studies felt they did not know enough about the potential dangers associated with e-cigarettes to answer questions about perceived harm (Ambrose et al. 2014; Amrock et al. 2015). Although relative harm compared with cigarettes is important to assess, equally important is determining young people's perception of the absolute harm from e-cigarettes. National data show that only 23.6% of middle and high school students combined believed that e-cigarettes cause "a lot of harm" (Table 2.12a), and only 26.8% of young adults believed e-cigarettes are "very harmful" (Table 2.12d). However, significant differences emerge in these perceptions of harm when examined by whether or not youth and young adults use e-cigarettes. Among both middle and high school students and young adults, perceptions of "no harm" were much more prevalent among those with prior experience with e-cigarettes (Tables 2.12b–2.12d). Current e-cigarette users were two to three times more likely to report that e-cigarettes convey "no harm" compared to never e-cigarette users, for both age groups (Tables 2.12a and 2.12d).

The most commonly cited reasons that youth and young adults reported using e-cigarettes included curiosity (Schmidt et al. 2014; Biener and Hargraves 2015; Biener et al. 2015; Kong et al. 2015; McDonald and Ling 2015; Suris et al. 2015; Sutfin et al. 2015), flavorings/taste (Ambrose et al. 2015; University of Michigan 2015), use as a less harmful/less toxic alternative to conventional cigarettes (Peters et al. 2013; Tucker et al. 2014; Ambrose et al. 2015; Kong et al. 2015; McDonald and Ling 2015; Sutfin et al. 2015), and avoidance of indoor smoking restrictions or disturbing people with secondhand smoke from conventional cigarettes (Tucker et al. 2014; Ambrose et al. 2015; Kong et al. 2015; McDonald and Ling 2015; Suris et al. 2015; Sutfin et al. 2015). Using e-cigarettes as an aid to conventional cigarette smoking reduction/cessation (Li et al. 2013; Schmidt et al. 2014; Tucker et al. 2014) was not a primary motivator among youth and young adults. Youth and young adult smokers cited lack of satisfaction, poor taste, and cost (Kong et al. 2015) as reasons for discontinuing e-cigarette use. Additional research is needed to examine how reasons for use, including the appeal of flavored e-cigarettes, are causally related to the onset and progression of e-cigarette use among youth and young adults. Data from the first wave of the PATH study suggest that flavors may play an important role in the initiation of e-cigarette use among youth (Ambrose et al. 2015), while data from the 2014 NYTS (Corey et al. 2015) and 2013–2014 NATS

(Table 2.9) underscore that use of flavored e-cigarettes remains prevalent among youth and young adults who currently use e-cigarettes.

Conclusion

- 1) Among middle and high school students, both ever and past-30-day e-cigarette use have more than tripled since 2011. Among young adults 18–24 years of age, ever e-cigarette use more than doubled from 2013 to 2014 following a period of relative stability from 2011 to 2013.
- 2) The most recent data available show that the prevalence of past-30-day use of e-cigarettes is similar among high school students (16% in 2015, 13.4% in 2014) and young adults 18–24 years of age (13.6% in 2013–2014) compared to middle school students (5.3% in 2015, 3.9% in 2014) and adults 25 years of age and older (5.7% in 2013–2014).
- 3) Exclusive, past-30-day use of e-cigarettes among 8th-, 10th-, and 12th-grade students (6.8%, 10.4%, and 10.4%, respectively) exceeded exclusive, past-30-day use of conventional cigarettes in 2015 (1.4%, 2.2%, and 5.3%, respectively). In contrast—in 2013–2014 among young adults 18–24 years of age—exclusive, past-30-day use of conventional cigarettes (9.6%) exceeded exclusive, past-30-day use of e-cigarettes (6.1%). For both age groups, dual use of these products is common.
- 4) E-cigarette use is strongly associated with the use of other tobacco products among youth and young adults, particularly the use of combustible tobacco products. For example, in 2015, 58.8% of high school students who were current users of combustible tobacco products were also current users of e-cigarettes.
- 5) Among youth—older students, Hispanics, and Whites are more likely to use e-cigarettes than younger students and Blacks. Among young adults—males, Hispanics, Whites, and those with lower levels of education are more likely to use e-cigarettes than females, Blacks, and those with higher levels of education.
- 6) The most commonly cited reasons for using e-cigarettes among both youth and young adults are curiosity, flavoring/taste, and low perceived harm compared to other tobacco products. The use of e-cigarettes as an aid to quit conventional cigarettes is not reported as a primary reason for use among youth and young adults.
- 7) Flavored e-cigarette use among young adult current users (18–24 years of age) exceeds that of older adult current users (25 years of age and older). Moreover, among youth who have ever tried an e-cigarette, a majority used a flavored product the first time they tried an e-cigarette.
- 8) E-cigarette products can be used as a delivery system for cannabinoids and potentially for other illicit drugs. More specific surveillance measures are needed to assess the use of drugs other than nicotine in e-cigarettes.

SECTION 3. HEALTH EFFECTS OF E-CIGARETTE USE AMONG U.S. YOUTH AND YOUNG ADULTS

Introduction

This chapter focuses on the short-term and potential long-term health effects related to the incidence and continued use of electronic cigarettes (e-cigarettes) by youth and young adults. The sharp increase in the prevalence of e-cigarette use among youth and young adults, especially from 2011 to 2015 (Centers for Disease Control and Prevention [CDC] 2015, 2016), highlights the compelling need to learn more about this evolving class of products. This chapter highlights the scientific literature that addresses potential adverse health effects caused by direct exposure to aerosolized nicotine, flavorants, chemicals, and other particulates of e-cigarettes; secondhand exposure to e-cigarette aerosol; and exposure to the surface-deposited aerosol contaminants. Literature regarding harmful consequences of close contact with malfunctioning e-cigarette devices and ingestion of the nicotine-containing liquids (e-liquids) are also explored. This chapter examines available data on e-cigarettes and youth, reviews established human and animal data on harmful developmental effects of nicotine (prenatal and adolescent), and reviews data on e-cigarettes among adults when data on youth are not available. Of note, given the relatively recent emergence of e-cigarettes, data are not yet available that address the long-term health effects of use or exposure over several years compared with nonuse or exposure to air free from secondhand tobacco smoke and aerosol from e-cigarettes; thus, the discussion is limited in that regard.

Conclusions from Previous Surgeon General's Reports

This chapter comprehensively reviews a new and emerging body of scientific evidence related to the use of e-cigarettes by youth and young adults. The enormous knowledge base on tobacco smoking and human health is also relevant to this discussion. That literature, which has been accumulating for more than 50 years, provides incontrovertible evidence that smoking is a cause of disease in almost every organ of the body (U.S. Department of Health and Human Services [USDHHS] 2004, 2014). Laboratory research has characterized the components of tobacco smoke and probed the mechanisms by which these constituents cause addiction and injury to cells, tissues, organs, and the developing fetus.

The evidence on the harmful consequences of nicotine exposure in conventional cigarettes, including addiction, and other adverse effects, is particularly relevant to e-cigarettes. Nicotine doses from e-cigarettes vary tremendously depending on characteristics of the user (experience with smoking conventional cigarettes or e-cigarettes), technical aspects of the e-cigarette, and levels of nicotine in the e-liquid. Although studies of nicotine doses in youth and young adults are lacking, studies of adults have found delivery of nicotine from e-cigarettes in doses ranging from negligible to as large as (Lopez et al. 2016; Vansickel and Eissenberg 2013; Spindle et al. 2015; St. Helen et al. 2016) or larger than (Ramôa et al.

2016) conventional cigarettes. Similarly, passive exposure to secondhand nicotine from e-cigarettes is just as large (Flouris et al. 2013) or lower than (Czogala et al. 2014) conventional cigarettes.

The findings of scientific research on smoking and involuntary exposure to tobacco smoke have been reviewed thoroughly in the 32 reports on smoking and health produced by the Surgeon General to date (there is one report on smokeless tobacco) (Table 3.1). The landmark first report was published in 1964 (U.S. Department of Health, Education, and Welfare [USDHEW] 1964), and the 50th-anniversary report, released in January 2014, comprehensively covered multiple aspects of cigarette smoking and health and lengthened the list of diseases caused by smoking and involuntary exposure to tobacco smoke (USDHHS 2014). Other Surgeon General's reports that are particularly relevant to the present report include reports on the health consequences of smoking and involuntary exposure to tobacco smoke (USDHHS 2004, 2006), on the mechanisms by which smoking causes disease (USDHHS 2010), and on the health consequences of smoking on youth and young adults (USDHHS 1994, 2012). The Surgeon General's reports on smoking and health have provided powerful conclusions on the dangers of nicotine. The 1988 report, released by Surgeon General C. Everett Koop, was the first to characterize smoking as addictive, and it identified nicotine as "...the drug in tobacco that causes addiction" (Appendix 3.1)³ (USDHHS 1988, p. 9).

Subsequent reports expanded on the conclusions in the 1988 report related to nicotine—reaffirming that nicotine causes addiction, describing nicotine's effects on key brain receptors (USDHHS 2010), and emphasizing that youth are more sensitive to nicotine than adults and can become dependent to nicotine much faster than adults (USDHHS 2012). This is of particular concern in the context of e-cigarettes because blood nicotine levels in e-cigarette users have been reported as being comparable to or higher than levels in smokers of conventional cigarettes (Lopez et al. 2016; Spindle et al. 2015), and serum cotinine (a nicotine metabolite) levels have been reported as being equal to that found in conventional cigarette users (Etter 2016; Marsot and Simon 2016). Because of their sensitivity to nicotine and subsequent addiction, about 3 out of 14 young smokers end up smoking into adulthood, even if they intend to quit after a few years; among youth who continue to smoke as adults, one-half will die prematurely from smoking (Peto et al. 1994; CDC 1996; Hahn et al. 2002; Doll et al. 2004). Surgeon General's reports have also emphasized the critical role of environmental determinants of tobacco use, including the causal roles of the tobacco industry's advertising and promotional activities and of the peer social environment (USDHHS 2012).

The 2014 Surgeon General's report included a chapter that addressed the numerous adverse consequences of nicotine other than addiction (USDHHS 2014).

The review documented the broad biological activity of nicotine, which can activate multiple biological pathways, and the adverse effects of nicotine exposure during pregnancy on fetal development and during adolescence on brain development. Of concern with regard to current trends in e-cigarette use among youth and young adults, the evidence suggests that exposure to nicotine during this period of life may have lasting deleterious consequences for brain development, including detrimental effects on cognition (USDHHS 2014).

³ All appendixes and appendix tables that are cross-referenced in this chapter are available only online at <http://www.surgeongeneral.gov/library/reports/>.

Table 3.1. Relevant conclusions from previous Surgeon General's reports on smoking and health

Report	Year	Conclusions
<i>The Health Consequences of Smoking: Nicotine Addiction</i> (USDHHS 1988, p. 9)	1988	Major Conclusions 1. Cigarettes and other forms of tobacco are addicting. 2. Nicotine is the drug in tobacco that causes addiction. 3. The pharmacologic and behavioral processes that determine tobacco addiction are similar to those that determine addiction to drugs such as heroin and cocaine.
<i>How Tobacco Smoke Causes Disease: The Biology and Behavioral Basis for Smoking-Attributable Disease</i> (USDHHS 2010, p. 183)	2010	Chapter 4. Nicotine Addiction: Past and Present 1. Nicotine is the key chemical compound that causes and sustains the powerful addicting effects of commercial tobacco products. 2. The powerful addicting effects of commercial tobacco products are mediated by diverse actions of nicotine at multiple types of nicotinic receptors in the brain. 3. Evidence is suggestive that there may be psychosocial, biologic, and genetic determinants associated with different trajectories observed among population subgroups as they move from experimentation to heavy smoking. 4. Inherited genetic variation in genes such as <i>CYP2A6</i> contributes to the differing patterns of smoking behavior and smoking cessation. 5. Evidence is consistent that individual differences in smoking histories and severity of withdrawal symptoms are related to successful recovery from nicotine addiction.
<i>Preventing Tobacco Use Among Youth and Young Adults</i> (USDHHS 2012, pp. 8, 460)	2012	Major Conclusions 1. Cigarette smoking by youth and young adults has immediate adverse health consequences, including addiction, and accelerates the development of chronic diseases across the full life course. 2. Prevention efforts must focus on both adolescents and young adults because among adults who become daily smokers, nearly all first use of cigarettes occurs by 18 years of age (88%), with 99% of first use by 26 years of age. 3. Advertising and promotional activities by tobacco companies have been shown to cause the onset and continuation of smoking among adolescents and young adults. 4. After years of steady progress, declines in the use of tobacco by youth and young adults have slowed for cigarette smoking and stalled for smokeless tobacco use. 5. Coordinated, multicomponent interventions that combine mass media campaigns, price increases including those that result from tax increases, school-based policies and programs, and statewide or community-wide changes in smokefree policies and norms are effective in reducing the initiation, prevalence, and intensity of smoking among youth and young adults. Chapter 4. Social, Environmental, Cognitive, and Genetic Influences on the Use of Tobacco among Youth 1. Given their developmental stage, adolescents and young adults are uniquely susceptible to social and environmental influences to use tobacco. 2. Socioeconomic factors and educational attainment influence the development of youth smoking behavior. The adolescents most likely to begin to use tobacco and progress to regular use are those who have lower academic achievement. 3. The evidence is sufficient to conclude that there is a causal relationship between peer group social influences and the initiation and maintenance of smoking behaviors during adolescence. 4. Affective processes play an important role in youth smoking behavior, with a strong association between youth smoking and negative affect. 5. The evidence is suggestive that tobacco use is a heritable trait, more so for regular use than for onset. The expression of genetic risk for smoking among young people may be moderated by small-group and larger social-environmental factors.
<i>The Health Consequences of Smoking—50 Years of Progress</i> (USDHHS 2014, p. 126)	2014	Chapter 5: Nicotine 1. The evidence is sufficient to infer that at high-enough doses nicotine has acute toxicity. 2. The evidence is sufficient to infer that nicotine activates multiple biological pathways through which smoking increases risk for disease. 3. The evidence is sufficient to infer that nicotine exposure during fetal development, a critical window for brain development, has lasting adverse consequences for brain development. 4. The evidence is sufficient to infer that nicotine adversely affects maternal and fetal health during pregnancy, contributing to multiple adverse outcomes such as preterm delivery and stillbirth. 5. The evidence is suggestive that nicotine exposure during adolescence, a critical window for brain development, may have lasting adverse consequences for brain development. 6. The evidence is inadequate to infer the presence or absence of a causal relationship between exposure to nicotine and risk for cancer.

Note: USDHHS = U.S. Department of Health and Human Services.

Finally, the aerosol from e-cigarettes may include other components that have been addressed in previous Surgeon General's reports, such as tobacco-specific nitrosamines (TSNAs), acrolein, and formaldehyde (USDHEW 1979; USDHHS 2010). Aerosols generated with vaporizers contain up to 31 compounds, including nicotine, nicotyrine, formaldehyde, acetaldehyde glycidol, acrolein, acetol, and diacetyl (Sleiman et al. 2016). Glycidol is a probable carcinogen not previously identified in the vapor, and acrolein is a powerful irritant (Sleiman et al. 2016). Although these constituents have been identified in e-cigarette aerosol, current evidence is unclear on whether typical user dosages achieve levels as high as conventional cigarettes, or at harmful or potentially harmful levels. More information will be available in the coming years as e-cigarette manufacturers begin reporting harmful or potential harmful constituents in compliance with the Tobacco Control Act.

Health Effects of E-Cigarette Use

The potential adverse health effects for youth who inhale e-cigarette aerosol include those on the body from acute administration of nicotine, flavorants, chemicals, other particulates, and additional effects, such as (1) nicotine addiction; (2) developmental effects on the brain from nicotine exposure, which may have implications for cognition, attention, and mood; (3) e-cigarette influence initiating or supporting the use of conventional cigarettes and dual use of conventional cigarettes and e-cigarettes; (4) e-cigarette influence on subsequent illicit drug use; (5) e-cigarette effects on psychosocial health, particularly among youth with one or more comorbid mental health disorders; and (6) battery explosion and accidental overdose of nicotine.

Effects of Aerosol Inhalation by the E-Cigarette User

Determining the potential health effects of inhaling e-cigarette aerosol is challenging due to the number of possible combinations of customizable options (Seidenberg et al. 2016), including battery power, nicotine concentration, e-liquids (Goniewicz et al. 2015; Buettner-Schmidt et al. 2016), and use behaviors and puff topography (Dawkins et al. 2016; Lopez et al. 2016). The amount of nicotine, flavorants, and other e-liquid constituents in e-cigarettes available for consumers to purchase varies widely, and the aerosolized constituents delivered vary by the type and voltage of the e-cigarette device being used (Cobb et al. 2015). Studies of commercial products have shown that e-liquids can contain as little as 0 milligrams/milliliter (mg/mL) to as much as 36.6 mg/mL of nicotine (Goniewicz et al. 2015); can be mislabeled (Peace et al. 2016); can vary by propylene glycol (PG)/vegetable glycerin (VG) ratio; and can contain one or more of several thousand available flavorants (Zhu et al. 2014b). Some liquids intended for use in e-cigarettes contain adulterants not named on ingredient lists (Varlet et al. 2015), and under at least some user conditions, the aerosolization process, which involves heating, produces additional toxicants that may present health risks (Talih et al. 2015). The sections that follow comprehensively cover the effects of inhaling aerosolized nicotine and then consider what is known about solvents (i.e., PG and VG, flavorants, and other chemicals) added to e-cigarettes, adulterants in e-liquids formed in the nicotine extraction process (e.g., *N*-nitrosonornicotine), and toxicants formed during the heating and aerosolization process (e.g., acrolein and formaldehyde) (Sleiman et al. 2016).

Dose and Effects of Inhaling Aerosolized Nicotine

Nicotine addiction via e-cigarette use is a primary public health concern due to the exponential growth in e-cigarette use among youth. The potential for widespread nicotine addiction among youth is high, as are the harmful consequences of nicotine on fetal development and the developing adolescent brain (USDHHS 2014). Nicotine, a psychomotor stimulant drug, is the primary psychoactive and addictive constituent in the smoke of conventional cigarettes and an important determinant in maintaining smoking dependence (e.g., USDHHS 2014). E-liquids typically contain nicotine, although in more widely variable concentrations than those found in conventional cigarettes (Trehy et al. 2011; Cameron et al. 2014; Cheng 2014; Goniewicz et al. 2015; Marsot and Simon 2016). The concentration of liquid nicotine is only one factor that influences the amount of aerosolized nicotine available for inhalation (Lopez et al. 2016); other factors include the power of the device being used (e.g., battery voltage, heater resistance) and user behavior (e.g., puff duration, interpuff interval) (Shihadeh and Eissenberg 2015; Talih et al. 2016; Etter 2016). The interplay of these factors may help to explain the variability in plasma nicotine concentration when adults use e-cigarettes under controlled conditions which can be higher (Ramôa et al. 2016), lower (Bullen et al. 2010; Vansickel et al. 2010, 2012; Farsalinos et al. 2014b; Nides et al. 2014; Oncken et al. 2015; Yan and D’Ruiz 2015), or similar to those obtained by smoking conventional cigarettes (Vansickel and Eissenberg 2013; Spindle et al. 2015; St. Helen et al. 2016; see Figure 3.1). Generalization across studies is difficult due to variations in devices, e-liquids, and e-cigarette use behavior within the study sample. As demonstrated in Figure 3.1, in studies where a variety of products were used under similar laboratory conditions (i.e., blood sampling before and immediately after a 10-puff episode), there was wide variability in nicotine delivery between devices, with “cigalike” products (cigarette-like products) delivering less nicotine than “tank” products (Farsalinos et al. 2014b; Yan and D’Ruiz 2015), and low-resistance, dual-coil “cartomizer” products having the capacity to deliver less or more nicotine than a conventional cigarette, depending on the concentration of liquid nicotine (Ramôa et al. 2016).

When the device type and liquid dose were held constant in a controlled session in one study, plasma nicotine concentrations (in this case in nanograms [ng]/mL) varied considerably across participants (0.8 to 8.5 ng/mL) (Nides et al. 2014). This variation was likely attributable to the manner in which the users puffed when using e-cigarettes, or that person’s “puff topography,” which includes the number of puffs, the intake volume and duration, the interpuff interval, and the flow rate (Zacny and Stitzer 1988; Blank et al. 2009).

Available data suggest that puff durations among adult cigarette smokers who are new e-cigarette users are comparable to those observed with conventional cigarettes (at least about 2 seconds [sec]) (Farsalinos et al. 2013b; Hua et al. 2013; Norton et al. 2014). However, puff durations during e-cigarette use among experienced e-cigarette users may be twice as long (~4 sec) (Farsalinos et al. 2013b; Hua et al. 2013; Spindle et al. 2015) as puff duration during conventional cigarette use. Puff duration is directly related to the nicotine content of the e-cigarette aerosol (i.e., the yield or dose) (Talih et al. 2016), suggesting that smokers of conventional cigarettes who switch to e-cigarettes may increase the duration of their puffs when using the new product in an attempt to extract more nicotine. Research also suggests that cigarette smokers may learn to alter other aspects of their puffing behavior when using an e-cigarette (Spindle et al. 2015). Relative to smokers of conventional cigarettes (Kleykamp et al. 2008), experienced e-cigarette users were found to have puff volumes that were

significantly higher (101.4 mL vs. 51.3 mL) and puff flow rates that were significantly lower (24.2 mL/sec vs. 37.9 mL/sec) (Spindle et al. 2015). In a different study, adult cigarette smokers who had never used e-cigarettes but switched to e-cigarettes showed significantly increased puff durations and decreased puff flow rates within 1 week (Lee et al. 2015). Elsewhere, adult cigarette smokers given an e-cigarette appeared to show an enhanced ability to extract nicotine from their device after 4 weeks of use (Hajek et al. 2015). Thus, the health effects of aerosolized nicotine in e-cigarette users may depend on a variety of factors, including the e-liquid used, the user's behavior, and the user's experience with the product.

Aerosolized Nicotine and Cardiovascular Function

Smoking is a major cause of death from cardiovascular disease (USDHHS 2014), and exposure to nicotine has been identified as a potential initiating factor in the atherogenic process (Lee et al. 2011; Santanam et al. 2012; Benowitz and Burbank 2016). Acute administration of nicotine causes a variety of well-characterized, dose- and route-dependent effects in adults, including cardiovascular effects, such as increases in heart rate and blood pressure (BP) and greater cardiac output, leading to an increase in myocardial oxygen demand (Rosenberg et al. 1980; USDHHS 2014). Reports from cell biology and animal studies have established biologic plausibility between nicotine alone and negative cardiovascular effects (Hanna 2006; Santanam et al. 2012). These studies have shown that nicotine induces the production of various inflammatory mediators involved with atherosclerotic pathogenesis (Lau and Baldus 2006), and that at the cellular level, nicotine induces C-reactive protein (CRP) expression in macrophages that contribute pro-inflammatory and pro-atherosclerotic effects (Mao et al. 2012).

Long-term studies on the safety of nicotine-only exposure (e.g., as with using e-cigarettes rather than smoking conventional cigarettes) among youth have not been conducted, and little is known about the cardiovascular effects of e-cigarette use among adults. However, when e-cigarettes are accompanied by a measurable increase in plasma nicotine concentration, it increases heart rate (Vansickel et al. 2012; Vansickel and Eissenberg 2013; Nides et al. 2014; Yan and D'Ruiz 2015), and diastolic BP rises.

Given the paucity of long-term data on the impact of e-cigarette smoking in relation to cardiovascular disease, other nicotine products offer a useful analogy. A meta-analysis reported that replacing the consumption of conventional cigarettes with nicotine replacement therapy (NRT) reduces cardiovascular risk among former smokers without significant adverse consequences (compared with current smokers) (Greenland et al. 1998; Moore et al. 2009). However, most NRT use is temporary (<26 months), and the adverse consequences of longer term NRT therapy are unknown.

Elsewhere, investigators examined the relationship between the use of Swedish-type moist snuff (or "snus"), which contains high levels of nicotine and low levels of TSNA, and the incidence of acute myocardial infarction among men with a mean age of 35 years who had never smoked cigarettes. The researchers, who pooled data from eight prospective cohort studies, found no support for any association between the use of snus and the development of acute myocardial infarction (Hansson et al. 2012), regardless of timing, intensity, duration, or period of use among the men who were followed for 4–29 years.

In summary, despite overwhelming epidemiologic evidence linking the use of conventional cigarettes with cardiovascular disease, the precise components of cigarette smoke responsible for this relationship and the mechanisms by which they exert their effects

have not yet been fully explained (Hanna 2006). For e-cigarettes, biological data support a potential association with cardiovascular disease, and short-term use of these products is accompanied by a measurable increase in plasma nicotine concentrations in adults as well as increases in heart rate and blood pressure. Much more research is needed, but the limited data available suggest the typical cardiovascular effects exerted by nicotine are also exerted by e-cigarettes (Benowitz and Burbank 2016; Bhatnagar 2016).

Aerosolized Nicotine and Dependence

Although a great deal is known about self-administration of nicotine and the development of nicotine dependence among adults (USDHHS 2014) and youth (Colby et al. 2000; USDHHS 2012; O’Loughlin et al. 2014; Yuan et al. 2015), more research is needed on nicotine dependence in youth and young adults as a result of using e-cigarettes. Nicotine dependence, also referred to as nicotine addiction (USDHHS 2010) or tobacco use disorder (American Psychiatric Association [APA] 2013), is defined as a neurobiological adaptation to repeated drug exposure that is manifested behaviorally by highly controlled or compulsive use; psychoactive effects such as tolerance, physical dependence, and pleasant effect; and nicotine-reinforced behavior, including an inability to quit despite harmful effects, a desire to quit, and repeated cessation attempts (USDHHS 1988; APA 2013). In tobacco-dependent users of conventional cigarettes, a predictable consequence of short-term abstinence (e.g., for more than a few hours) is the onset of withdrawal symptoms indicated by self-reported behavioral, cognitive, and physiological symptoms and by clinical signs (USDHHS 2010). Subjective withdrawal symptoms are manifested by affective disturbance, including irritability and anger, anxiety, and depressed mood. The behavioral symptoms include restlessness, sleep disturbance, and increased appetite. Cognitive disturbances usually center on difficulty in concentrating (USDHHS 2010).

Early studies of conventional cigarette smokers using e-cigarettes reported poor nicotine delivery with little to no increase in blood nicotine levels after puffing (Eissenberg 2010; Vansickel et al. 2010). Later studies reported that the effect on serum cotinine levels among new e-cigarette users can be similar to that generated by conventional cigarettes (Flouris et al. 2013; Lopez et al. 2016). Studies examining this discrepancy found that e-cigarette users require longer puffs to deliver equivalent nicotine doses (Lee et al. 2015), and within a week, inexperienced e-cigarette users adjust their puffing patterns after switching (Hua et al. 2013b; Lee et al. 2015; Talih et al. 2015).

In more experienced e-cigarette users, blood nicotine levels appear to be influenced by puffing patterns, such as puff length. Volume and frequency and plasma nicotine levels ranging from 2.50 to 13.4 ng/mL have been observed after 10 puffs of an e-cigarette (Dawkins and Corcoran 2014). Dawkins and colleagues (2016) used 24 mg/mL nicotine strength liquid and observed high blood nicotine levels that were achieved very quickly, matching and even exceeding those reported in conventional cigarette smokers. St. Helen and colleagues (2016) conducted a similar study and reported that e-cigarettes can deliver levels of nicotine that are comparable to or higher than conventional cigarettes. Finally, Etter (2016) reported cotinine levels among experienced e-cigarette users similar to levels usually observed in conventional cigarette smokers. Figure 3.1 and Table A3.1-1 in Appendix 3.1 summarize studies on aerosolized nicotine from e-cigarettes and dependence using dependency criteria.

Source: Vansickel et al. (2010); Farsalinos et al. (2014b); Yan and D’Ruiz (2015); and Ramôa et al. (2016).

Notes: Data for conventional cigarettes are from 32 tobacco cigarette smokers using their usual brand of cigarette (Vansickel et al. 2010). E-cigarette A is a cigalike called “blu” loaded with two different concentrations of liquid nicotine (16 or 24 mg/mL, both containing 20% propylene glycol and 50% vegetable glycerin). Data are from 23 smokers of tobacco cigarettes with 7 days of experience with the e-cigarette product (Yan and D’Ruiz 2015). E-cigarette B is a cigalike called “V2cigs,” and E-cigarette C is a “tank” product called “EVIC” with an “Evod” heating element; both were loaded with an 18 mg/mL liquid containing 34% propylene glycol and 66% vegetable glycerin. Data are from 23 experienced users of e-cigarettes (Farsalinos et al. 2014b). E-cigarette D uses a 3.3-volt “Ego” battery fitted with a 1.5-Ohm dual coil cartomizer (“Smoktech”) and filled with ~1 mL of a 70% propylene glycol, 30% vegetable glycerin liquid that varied by liquid nicotine concentration (0, 8, 18, or 36 mg/mL). Data are from 16 experienced users of e-cigarettes (Ramôa et al. 2016).

Figure 3.1. Plasma nicotine concentration from different human laboratory studies and four different products with blood sampled before and immediately after a 10-puff bout with the products.

The ability of e-cigarettes to deliver comparable or higher amounts of nicotine compared to conventional cigarettes raises concerns about e-cigarette use generating nicotine dependence among young people (Dawkins et al. 2016; Etter 2016; St. Helen et al. 2016). The reported blood levels of nicotine, or cotinine, in e-cigarette users is likely to cause physiological changes in nicotinic acetylcholine receptors in the brain that would sustain nicotine addiction (Kandel and Kandel 2014; Yuan et al. 2015). This is particularly

concerning for adolescents and young adults, given that early exposure to nicotine increases the severity of future nicotine dependence (St. Helen et al. 2016; USDHHS 2014).

Symptoms of nicotine dependence can occur soon after the initiation of conventional smoking, and even before established use, among adolescents and young adults (DiFranza et al. 2002; O'Loughlin et al. 2003; Dierker et al. 2007; Ramôa et al. 2016). Furthermore, some adolescents have reported nicotine dependence symptoms while using tobacco as little as 1–3 days per month (Rose et al. 2010). Using the National Comorbidity Survey-Adolescent dataset, Dierker and colleagues (2012) reported that nicotine dependence in adolescents was likely to occur within 1 year of the initiation of weekly or daily smoking, regardless of sociodemographic variables. Importantly, when smoking onset began at a younger age, the transition to weekly and daily smoking was more rapid, indicating a youthful neurobiological sensitivity to nicotine (Dierker et al. 2012). Zhan and colleagues (2012) found that symptoms of nicotine dependence could be detected among teenagers before they had smoked even 100 cigarettes.

Because few validated measures exist for assessing dependence on e-cigarette use, some researchers have adapted those originally developed to measure dependence in smokers of conventional cigarettes. Among adults, scores on these measures have been consistently lower in e-cigarette users than in smokers of conventional cigarettes (Farsalinos et al. 2013a; Etter and Eissenberg 2015; Foulds et al. 2015). Still, scores for e-cigarette dependence among former cigarette smokers were positively associated with the nicotine concentration of the e-cigarette liquid and the type of device used (Etter 2015; Etter and Eissenberg 2015; Foulds et al. 2015). Research in this area is challenging to interpret because measurement of youth e-cigarette dependence has not been standardized and there is a wide variation in device/e-liquid combinations, which allow for adjustable nicotine delivery among study participants. Regardless, among 766 adults, who were daily users of e-cigarettes (with nicotine) and who were either former cigarette smokers (83%) or current cigarette smokers (17%), 30.7% indicated that they would likely be unable to stop using e-cigarettes, 28.2% that they would find it “very difficult” or “impossible” to stop using e-cigarettes, and 27.5% that they were unable to stop e-cigarette use (Etter and Eissenberg 2015). However, it is important to note that e-cigarettes were less addictive than conventional cigarettes in this sample (Etter and Eissenberg 2015).

In summary, the addictive liability of e-cigarettes has the potential to be at least equivalent to that of conventional cigarettes, given nicotine dose levels produced by these products, particularly among experienced users operating new-generation devices (Ramôa et al. 2016). More generally, the delivery of nicotine in sufficient doses and blood concentration would be expected to produce and maintain dependence in e-cigarette users. Further work would be useful to determine the natural course and history of e-cigarette use among smokers of conventional cigarettes, former smokers, and never smokers and to more accurately determine the nicotine addiction liability of e-cigarette use. Unfortunately, these issues have not been explored in adolescents, although the prevalence of e-cigarette use has increased considerably in that population since 2011 (see Chapter 2).

Effects of Nicotine in Youth Users

Nicotine is the prime psychoactive substance in conventional cigarettes (Yuan et al. 2015), and given that the developing adolescent brain is immature and vulnerable to neurobiological insults (Bernheim et al. 2013; Lydon et al. 2014), it is important to

understand how nicotine delivered by e-cigarette use affects adolescent brain development and how responses to nicotine in adolescents differ from those seen in adults. Substantial evidence suggests that nicotine can negatively influence both adolescent and prenatal brain development (USDHHS 2014). For example, Weiss and colleagues (2008) reported a strong mechanistic link among early nicotine exposure (younger than 16 years of age), common genes related to the severity of nicotine addiction (CHRNA5-A3-B4 haplotypes), and adult nicotine addiction in three independent populations of European origins. Although much of the literature on nicotine addiction arises from studies of nicotine exposure among adults, and with combustible tobacco products (see Table A3.1-2 in Appendix 3.1), there is a growing body of biological mechanistic literature from animal studies that model the effects of nicotine in doses equivalent to those for humans (see Table A3.1-3 in Appendix 3.1). These animal and human studies, taken together with studies of rising e-cigarette prevalence in youth (see Chapter 2), point to an age-dependent susceptibility to nicotine as a neurobiological insult.

Limited direct human experimental data exist on the effects of nicotine exposure from e-cigarettes on the developing adolescent brain, but experimental laboratory data have been found to be relevant in animal models to contextualize effects in humans (Stevens and Vaccarino 2015). Even if the full complexity of human brain development and behavioral function during adolescence cannot be completely modeled in other species, the similarities across adolescents of different species support the use of animal models of adolescence when examining neural and environmental contributors to adolescent-characteristic functioning (Spear 2010).

Animal studies provide an effective method to examine the persistent effects of prenatal, child, and adolescent nicotine exposure, in addition to human epidemiologic data. When considering an epidemiologic causal argument of exposure (risk factor) to health outcome (disease), one should note that animal models lend biological plausibility when experimentation with humans is not possible (or ethical) (Rothman et al. 2008). Furthermore, animal studies offer significant advantages compared to human studies—with the ability to control for many confounding factors, to limit nicotine exposure to differing levels of physical and neural development—and are pivotal for understanding the neural substrates associated with adolescence. The validity of any causal argument when examining animal models requires careful consideration, and yet in combination with epidemiologic data—such as prevalence, incidence, and strength of association between exposure and outcome—a causal argument can be constructed with literature from animal models representing biologic plausibility. Using a variety of study designs and research paradigms including humans and animals, research in this area provides evidence for neuroteratogenic and neurotoxic effects on the developing adolescent brain (Lydon et al. 2014; England et al. 2015).

The brain undergoes significant neurobiological development during adolescence and young adulthood, which are critical periods of sensitivity to neurobiological insults (such as nicotine) and experience-induced plasticity (Spear 2000; Dahl 2004; Gulley and Juraska 2013). Although maturation occurs in different regions of the brain at different rates, a similar progression occurs in all areas characterized by a rapid formation of synaptic connections in early childhood, followed by a loss of redundant or unnecessary synapses (called pruning) and the formation of myelin. Myelination is the process by which a fatty layer, called myelin, accumulates around nerve cells (neurons). Because of myelin, nerve cells can transmit information faster, allowing for more complex brain processes. Pruning allows for more

focused concentration, and myelination allows for faster electrical and neural signaling; both allow for more efficient cognitive processing. During adolescence and into young adulthood, myelination occurs rapidly in the frontal lobe, a place in the brain that controls executive functioning, reasoning, decision-making skills, self-discipline, and impulse control. Plasticity refers to the current understanding that the brain continues to change throughout life, not only because of normal, maturational neural growth and development but also because of changes in environmental neurobiological exposures (such as nicotine), injuries, behaviors, thinking, and emotions (Mills and Tamnes 2014).

Across species, and in humans, adolescence is a key period of increased plasticity and rapid growth of brain circuits that regulate social, emotional, and motivational processes and decision making (Spear 2000, 2011; Nelson et al. 2005; Ernst and Fudge 2009; Counotte et al. 2011). The prefrontal cortex, which is involved in higher level regulatory control of complex behaviors (such as planning, impulse control, and working memory), continues normal structural and functional development into young adulthood, to about 25 years of age (Giedd and Rapoport 2010; Somerville and Casey 2010). Because of the immaturity and rapid growth of the prefrontal cortex, adolescents and young adults normally exhibit moody, risk-taking, and unpredictable impulsive behaviors. The combination of delayed maturation of frontal cognitive control and increased reactivity of subcortical reward-related and emotion-processing systems may lead to increased risk-taking behavior and a greater susceptibility to initiating substance use and the development of dependence (Steinberg 2008; Ernst and Fudge 2009; Counotte et al. 2011; Spear 2011). Thus, myelination is vitally important to the healthy functioning of the central nervous system, and any exposure that significantly interferes with the myelination process can cause mild-to-severe cognitive and learning problems (Brady et al. 2012).

Brain development in juvenile rodents has been reported to display patterns that resemble those of human beings, suggesting that the rodent model might be relevant to studying the neurobiological underpinnings of brain maturation in teenagers (Spear 2000). Studies across species have revealed unique characteristics of adolescent nonhuman brain structure, mechanisms, and function that provide biological plausibility to the hypothesis that human adolescents are particularly vulnerable to nicotine uptake (O'Loughlin et al. 2015; Yuan et al. 2015). There is evidence for rapid growth of gray matter, followed by activity-dependent synaptic pruning (the process of synapse elimination that occurs between early childhood and the onset of puberty) and increasing myelination throughout the brain (Casey et al. 2005; Lenroot and Giedd 2006; Giedd and Rapoport 2010; Counotte et al. 2011).

Nicotine has more significant and durable damaging effects on adolescent brains compared to adult brains, the former suffering more harmful effects. Preclinical animal studies have shown that in rodent models, nicotinic acetylcholine receptor (nAChR) signaling is still actively changing during adolescence, with higher expression and functional activity of nAChRs in the forebrain of adolescent rodents compared to their adult counterparts (Britton et al. 2007; Kota et al. 2007; Doura et al. 2008). Furthermore, in rodent models, nicotine actually enhances neuronal activity in several reward-related regions and does so more robustly in adolescents than in adults (Schochet et al. 2005; Shram et al. 2007; Dao et al. 2011). This increased sensitivity to nicotine in the reward pathways of adolescent rats is associated with enhanced behavioral responses, such as strengthening the stimulus-response reward for administration of nicotine. In conditioned place-preference tests—where reward is measured by the amount of time animals spend in an environment where they receive nicotine

compared to an environment where nicotine is not administered—adolescent rodents have shown an increased sensitivity to the rewarding effects of nicotine at very low doses (0.03 mg/kg) (Vastola et al. 2002; Belluzzi et al. 2004; Brielmaier et al. 2007; Kota et al. 2007; Natarajan et al. 2011) and exhibited a unique vulnerability to oral self-administration during the early-adolescent period (Adriani et al. 2002). Adolescent rodents also have shown higher levels of nicotine self-administration than adults (Levin et al. 2003; Chen et al. 2007; Natividad et al. 2013), decreased sensitivity to the aversive effects of nicotine (Adriani et al. 2002; Shram et al. 2006; Torres et al. 2008), and less prominent withdrawal symptoms following chronic nicotine exposure (O'Dell et al. 2006). This characteristic in rodent models of increased positive and decreased negative short-term effects of nicotine during adolescence (versus adulthood) highlights the possibility that human adolescents might be particularly vulnerable to developing dependency to and continuing to use e-cigarettes. These biological mechanisms are of great public health importance as exposure to nicotine grows among nonsmoking youth through the increasing prevalence of e-cigarette use.

Beyond their unique vulnerability to nicotine use, and thus smoking uptake, human adolescents may be particularly vulnerable to the detrimental consequences of nicotine exposure, including an increase in drug-seeking behaviors (Kandel and Kandel 2014), deficits in attention and cognition, and mood disorders (Yuan et al. 2015). In animal models, chronic nicotine exposure during adolescence has been shown to produce long-lasting, unique effects that are not observed in mature adult animals. Moreover, animal models have provided substantial evidence that the limbic system—which controls cognition, emotion, and drug-reward—is actively maturing during adolescence and during this age is vulnerable to long-term modification by nicotine.

Reward-Seeking Behaviors

A very strong argument can be made about the association between adolescent exposure to nicotine by smoking conventional cigarettes and the subsequent onset of using other dependence-producing substances. Strong, temporal, and dose-dependent associations have been reported (Isensee et al. 2003; John et al. 2004b; Bronisch et al. 2008; Kandel and Kandel 2015), and a plausible biological mechanism (via rodent and human modeling) suggests that long-term changes in the neural reward system take place as a result of adolescent smoking (Lewinsohn et al. 1999; Huang et al. 2013; Kandel and Kandel 2014). Adolescent smokers of conventional cigarettes have disproportionately high rates of comorbid substance abuse (Kandel et al. 1992; Lai et al. 2000; Hanna et al. 2001), and longitudinal studies have suggested that early adolescent smoking may be a starting point or “gateway” for substance abuse later in life (Kandel et al. 1992; Lewinsohn et al. 1999; Wagner and Anthony 2002; Brook et al. 2007), with this effect more likely for persons with attention deficit hyperactivity disorder (ADHD) (Biederman et al. 2006; Wilens et al. 2008). Although factors such as genetic comorbidity, innate propensity for risk taking, and social influences may underlie these findings (Lindsay and Rainey 1997; Smith et al. 2015), both human neuroimaging and animal studies suggest a neurobiological mechanism also plays a role. In addition, behavioral studies in adolescent and young adult smokers have revealed an increased propensity for risk taking, both generally and in the presence of peers, and neuroimaging studies have shown altered frontal neural activation during a risk-taking task as compared with nonsmokers (Lejuez et al. 2005; Cavalca et al. 2013; Galvan et al. 2013). Rubinstein and colleagues (2011b) used neuroimaging to show decreased brain response to a natural reinforcer

(pleasurable food cues) in adolescent light smokers (1–5 cigarettes per day), with their results highlighting the possibility of neural alterations consistent with nicotine dependence and altered brain response to reward even in adolescent low-level smokers.

Nicotine exposure in rodents at an age of physical development corresponding to human adolescence has been found to increase the reinforcing effects of other drugs of abuse, including cocaine, methamphetamine, and alcohol, without having a major impact on responding for other rewards, thus providing further evidence in support of nicotine as an initiation toward other substance use and abuse (McQuown et al. 2007; Dao et al. 2011; Dickson et al. 2014; Pipkin et al. 2014; Kandel and Kandel 2014). In several rodent studies, treatment with very low doses of nicotine for a few days during early adolescence, but not in late adolescence or adulthood, produced lasting changes in D2 and D3 dopamine receptors and in the selfadministration of other abused drugs (McQuown et al. 2007; Dao et al. 2011; Mojica et al. 2014). Nicotine exposure in adolescent rats also induced rapid and long-lasting dendritic remodeling in the nucleus accumbens shell, a critical component of reward learning and addiction, via a D1 dopamine receptor-mediated mechanism (Ehlinger et al. 2016). This persistent form of nicotine-induced neuroplasticity has the potential to alter synaptic connectivity within reward-processing centers and enhance the addictive effects of drugs of abuse.

Attention and Cognition

Both cognitive improvements (Jasinska et al. 2014) and cognitive deficits (Hall et al. 2014) have been reported after nicotine exposure in healthy human adults, while smoking during adolescence impairs cognition and attention processes. Results of a genetically sensitive, longitudinal “concordant” and “discordant” twin study from the Netherlands Twin Registry indicated a larger increase in attention problems from adolescence to adulthood in twins who smoked than in their never-smoking co-twins (Treur et al. 2015). In another study, adolescent smokers were found to have chronic impairments in the accuracy of their working memory (e.g., in processing information from two sensory modalities simultaneously), which were more severe with an earlier age of onset of smoking (Jacobsen et al. 2005). Functional imaging studies have shown that 24-hour smoking abstinence in adolescent smokers causes acute impairments of verbal memory and working memory, along with chronic decrements in cognitive performance (Jacobsen et al. 2007a). In another study, adolescent users of conventional cigarettes showed decreased prefrontal cortex activation (versus never smokers) during attention tasks, and duration of smoking (in years) was directly correlated with the extent of reduction in prefrontal cortical activity (Musso et al. 2007).

Thus, longitudinal and imaging studies in humans provide support for the hypothesis that adolescent use of conventional cigarettes has both acute and long-term effects on attention and memory. Although nicotine exposure cannot be cited as the sole cause of cognitive defects (or even one of several combined effects in humans), other studies have shown that adolescent nicotine exposure in rats induces lasting synaptic changes in the prefrontal cortical regions critical for normal attention, memory, and cognition that likely underlie observed impairments in attentional and cognitive function (Bergstrom et al. 2008). Adolescent nicotine exposure in rats has induced impairments in stimulus-response-discrimination-learning processes but not in abstract rule-learning processes, which are dependent on dissociable cognitive systems, thus showing the selective effects of nicotine (Pickens et al. 2013). In addition, adolescent, but not postadolescent, treatment of rats with nicotine resulted

in diminished attention span and enhanced impulsivity in adulthood (Counotte et al. 2009, 2011). The biological causes of these cognitive disturbances (reduced attention span and impulse control) were associated with reduced regulation of prefrontal cortex excitatory synapses function in metabotropic glutamate receptor 2 (mGluR2) (Counotte et al. 2011; Goriounova and Mansvelder 2012). In addition, hippocampal function, which is critical for memory, was altered in adult mice by nicotine exposure during adolescence. Contextual fear conditioning—a hippocampus-dependent task in which animals learn and remember to associate a fearful stimulus (e.g., a foot shock) with a particular context—was disrupted in adult mice that had been treated during adolescence with chronic nicotine but not following chronic treatment with nicotine in adulthood (Portugal et al. 2012). Rodent studies have implications for human adolescents, suggesting that exposure to tobacco during youth may lead to long-lasting changes in behavioral and neuronal plasticity into adulthood.

Mood Disorders

Adolescents with symptoms of mental health disorders (e.g., anxiety, aggressive and disruptive behaviors, mood disorders) are at increased risk for initiation of conventional cigarette use and long-term nicotine dependence compared with those without such disorders (Gehricke et al. 2007; Morris et al. 2011). Although this risk may reflect a common genetic predisposition, or the use of nicotine to self-medicate in the hope of improving mental health symptoms, the question arises of whether the smoking of conventional cigarettes by adolescents contributes to the development of mood disorders. A meta-analysis of existing studies showed consistent evidence that both tobacco use and dependence on tobacco products among adolescents indeed increased their risk of anxiety disorders (Moylan et al. 2012). Other studies have shown that an early onset of smoking is associated with a shorter time to first onset of an anxiety disorder (Jamal et al. 2011), and there is a positive association between adolescent smoking, particularly through a nicotine pathway, and anxiety in early adulthood (Moylan et al. 2013). Bidirectional relationships between adolescent smoking and disruptive disorders (e.g., ADHD; oppositional defiant disorder [ODD] [Griesler et al. 2011]) as well as depression (Tjora et al. 2014) also have been reported, while a longitudinal birth cohort found evidence to support a causal relationship between teen smoking and onset of depression (Boden et al. 2010). Although these findings are complex and warrant further study using comparisons of genetic polymorphisms associated with smoking or twin and sibling discordant/concordant studies (Munafo and Araya 2010; Leventhal and Zvolensky 2015), they do suggest that nicotine exposure during adolescence could contribute to long-term mental health disorders.

Findings of animal studies support the theory that adolescent nicotine exposure results in long-term alterations in emotional response, specifically enhanced anxiety and fear (Slawecki et al. 2003; Smith et al. 2006), and in persistent alterations in serotonin systems involved in mediating mood disorders by reprogramming the future response of 5-HT systems to nicotine (Slotkin and Seidler 2009). Even a single day of nicotine treatment in adolescent rats can enhance sensitivity to aversive stimuli later in life and result in a depression-like state in adulthood that is normalized by treatment with nicotine or antidepressants (Iniguez et al. 2009).

In summary, given the existing evidence from human and animal studies of the detrimental impact of nicotine exposure on adolescent brain development, the use of e-cigarettes by youth should be avoided and actively discouraged. Both preadolescence and

adolescence are developmental periods associated with increased vulnerability to nicotine addiction, and exposure to nicotine during these periods may lead to long-lasting changes in behavioral and neuronal plasticity. Studies reveal that for most tobacco users, initial use begins before 18 years of age. Moreover, in some adolescents, symptoms of nicotine dependence can develop after exposure to very low levels of nicotine—less than 100 cigarettes. Cross-species studies have identified characteristics of the adolescent brain that may render it vulnerable at this age to nicotine uptake in the form of equivalent doses via nonsmoking administration mechanisms. In addition, animal models of nicotine exposure in adolescence reveal neural and behavioral alterations consistent with an increased likelihood of future nicotine use, increased activation of reward pathways and, unlike in adult animals, decreased aversive effects. Regarding e-cigarettes, data demonstrate adolescent use of these devices is associated with use of tobacco, alcohol, and other drugs (Dutra and Glantz 2014; Kristjansson et al. 2015; Wills et al. 2015a, b; Schneider and Diehl 2016). Finally, animal and human studies suggest a bidirectional relationship between the smoking of conventional cigarettes and exposure to nicotine during adolescence and factors related to disruptive disorders, such as ADHD and ODD that impair academic performance, as well as to depression. Because the adolescent brain is still developing, nicotine use during adolescence can disrupt the formation of brain circuits that control attention, learning, and susceptibility to addiction. Further research is warranted to more fully understand the effects of e-cigarette use on youth.

Nicotine Exposure from Maternal Nicotine Consumption: Prenatal and Postnatal Health Outcomes

Prenatal nicotine exposure through maternal cigarette use during pregnancy is one of the most widespread perinatal insults in the world (Levin and Slotkin 1998; Xiao et al. 2008; USDHHS 2014). Despite medical and societal sanctions and ongoing public health campaigns, the prevalence of maternal cigarette use during pregnancy in the United States was estimated to be 11–15% in 2013 (Tong et al. 2013). Smoking rates were even higher among women who were poor, young, or less educated, with rates as high as 25–30%, indicating that infants born to mothers who are poor have disproportionately higher exposure to nicotine (Dietz et al. 2011; Hamilton et al. 2012; Tong et al. 2013). Despite these adverse consequences, an estimated one-half of pregnant smokers continue to smoke into the third trimester (Osterman et al. 2013; Tong et al. 2013).

Because adults who use e-cigarettes can achieve plasma nicotine concentrations similar to those found among smokers of equivalent amounts of conventional cigarettes (Vansickel et al. 2010; Lopez et al. 2016; St. Helen et al. 2016), it is important that research continues in this area. Nicotine has been shown to cross the placenta and has been found in placental tissue as early as 7 weeks of embryonic gestation, and nicotine concentrations are higher in fetal fluids than in maternal fluids (Luck et al. 1985; Jauniaux et al. 1999). nAChRs are widely distributed in the fetal brain. As has been clearly demonstrated in animal models, acetylcholine acts on nAChRs to modulate functional connections during critical periods of development when regions are most sensitive to environmental input (Dwyer et al. 2008). When nicotine in the maternal bloodstream crosses the placental barrier, it binds to these receptors (Pentel et al. 2006; Wong et al. 2015), and in rodents this can result in long-term changes in neural structure and function. Results from animal studies show consistent associations between prenatal nicotine exposure and upregulation of nAChRs associated with

disruption of fetal brain cell replication and differentiation (Slotkin 1998). Highlighting the role of nicotine in the effects of maternal smoking during pregnancy, nAChRs have been shown to be present in the human embryonic brain from 5 weeks of gestation (Hellstrom-Lindahl et al. 1998), and their normal maturation is altered in a region- and receptor subtype-dependent fashion by maternal cigarette smoking during pregnancy (Falk et al. 2005; Duncan et al. 2008). In those brainstem nuclei important for arousal, prenatal nicotine exposure decreases [3H]-nicotine binding (Duncan et al. 2008) and prevents normal age-related increases in $\alpha 4$ and $\alpha 7$ mRNA (Falk et al. 2005).

Prenatal nicotine exposure also has been associated with dysregulation of catecholaminergic, serotonergic, and other neurotransmitter systems. In addition, animal work suggests significant adverse effects of nicotine alone at levels commensurate with exposure to secondhand smoke (10-fold below those seen in active smokers), and that the non-nicotine components of tobacco smoke can exacerbate nicotine's teratogenic effects (Slotkin et al. 2015). Offermann (2015) concluded that e-cigarettes emit many harmful chemicals into the air and that indirect exposure to nicotine exceeded exposure-level standards for noncarcinogenic health effects established by the California Environmental Protection Agency. No safe level of prenatal nicotine exposure has been established (England et al. 2015).

Airborne nicotine exposure through secondhand aerosol from e-cigarettes has been observed, as has salivary cotinine concentrations of nonsmokers in the homes of e-cigarette users (Ballbe et al. 2014; Czogala et al. 2014). Ballbe and colleagues (2014) reported the geometric means of airborne nicotine were 0.74 $\mu\text{g}/\text{m}^3$ in the homes of smokers, 0.13 $\mu\text{g}/\text{m}^3$ in the homes of e-cigarette users, and 0.02 $\mu\text{g}/\text{m}^3$ in the homes of nonsmoking controls. While airborne nicotine exposure from combustible cigarette smoke was 5.7 (Ballbe et al. 2014) to 10 times higher (Czogala et al. 2014) than e-cigarette aerosol, one study reported only a twofold increase in salivary cotinine (0.38 ng/ml in the homes of smokers versus 0.19 ng/ml in the homes of e-cigarette users) (Ballbe et al. 2014), and another study found that exposure to cigarette smoke and exposure to e-cigarette aerosol had similar effects on the serum cotinine levels of bystanders (Flouris et al. 2013). Thus, the passive exposure to nicotine from e-cigarette smoking has been reported to be just as large (Flouris et al. 2013; Grana et al. 2013) or lower than (Czogala et al. 2014) conventional cigarettes, but exposure to nicotine from e-cigarette smoking is not negligible and is higher than in nonsmoking environments. This evidence suggests the importance of avoiding secondhand exposure of e-cigarette vapor and secondhand smoke during pregnancy (Flouris et al. 2013; Grana et al. 2013; Czogala et al. 2014).

Of the components of tobacco smoke, nicotine has been cited as the most important toxicant in terms of interfering with fetal development. Because of the health risks to the developing fetus associated with nicotine exposure during pregnancy, the U.S. Food and Drug Administration (FDA) (2015) recommends that pregnant women seek medical approval before using NRT, and the American College of Obstetricians and Gynecologists (2011) recommends consideration of NRT only if a woman fails behavioral interventions to quit smoking conventional cigarettes and has discussed the potential harms and benefits of NRT with her physician. NRT is most often used during pregnancy as a last resort to avoid exposing the fetus to the other toxic ingredients found in conventional tobacco smoke (Fiore et al. 2008). A Cochrane Database systematic review concluded that both the effectiveness and safety of NRT during pregnancy are unclear (Coleman et al. 2012). Table A3.1-4 in

Appendix 3.1 presents a summary of studies in humans on the effects of tobacco exposure on fetal brain development.

Even with a firm understanding of the negative health consequences of nicotine on the developing fetus (Fiore et al. 2008; USDHHS 2014; Ekblad et al. 2015), little is known about the prevalence of e-cigarette use among pregnant women or the direct harmful effects on their fetus by other toxicants delivered by the aerosol from e-cigarettes (England et al. 2015; Suter et al. 2015). In one of the few studies identified, a survey of 316 pregnant women in a Maryland clinic found that the majority had heard of e-cigarettes, 13% had ever used them, and 0.6% were current daily users (Mark et al. 2015). These findings are of concern because the dose of nicotine delivered by e-cigarettes can be as high or higher than that delivered by conventional cigarettes. Therefore, plasma nicotine concentrations delivered while using e-cigarettes have the potential to harm the developing fetus. Furthermore, in 2013 in the United States, there were 26.5 births for every 1,000 adolescent females (15–19 years of age), or 273,105 babies born to females in this age group (Hamilton et al. 2013). Currently, the rate of e-cigarette use among pregnant adolescents is unknown, but the effects of nicotine and the potential for harm by other e-cigarette toxicants indicate that the use of e-cigarettes is a fetal risk factor among pregnant adolescent girls.

As outlined below, the specific effects of nicotine on prenatal development and postnatal outcomes include sudden infant death syndrome (SIDS) and may include altered development of the corpus callosum, deficits in auditory processing, and alterations in appetitive behavior, attention, and cognition.

SIDS

SIDS is the sudden and unexplained death of an infant younger than 1 year of age (Krous 2014). Maternal smoking and infant exposure to secondhand smoke have been causally associated with SIDS, with 20–29% of deaths from SIDS attributable to maternal smoking of conventional cigarettes during pregnancy (Dietz et al. 2010; Zhang and Wang 2013; USDHHS 2014). Prenatal exposure to cigarettes and to smokeless tobacco have been associated with increased risk for apnea events, which have been linked to increased risk for SIDS (Gunnerbeck et al. 2011; Zhang and Wang 2013; Inamdar et al. 2015).

Although the mechanistic pathways underlying SIDS remain largely unknown, nicotine has effects on pathways that could be related to SIDS and is related to known risk factors, particularly lung and respiratory development (England et al. 2015; Holbrook 2016; Spindel and McEvoy 2016). Evidence from animal models supports the hypothesis that prenatal nicotine exposure alters both fetal autonomic function and arousal, which could increase the risk of SIDS (Slotkin 1998; Task Force on Sudden Infant Death Syndrome and Moon 2011). In humans, a dose–response relationship between cotinine (the major nicotine metabolite) and altered arousal patterns has been shown in preterm infants (Richardson et al. 2009), and this relationship is suggestive of nicotine’s role in arousal deficits that could be linked to SIDS. There is widespread distribution of nAChRs in the brainstem nuclei in both humans and animals that control cardiopulmonary integration and arousal in the newborn (Dwyer et al. 2008). In some animal studies, prenatal exposure to nicotine has increased mortality in newborns that were exposed to reduced oxygen (Slotkin et al. 1995; Fewell and Smith 1998). Prenatal exposure to nicotine is also associated with altered serotonin signaling in the brainstem in the rat model, leading to an exaggerated trigeminocardiac reflex and resulting in bradycardia, hypotension, and apnea (Gorini et al. 2013).

Altered Development of the Corpus callosum

The corpus callosum, the largest white matter structure in the brain, facilitates communication between the left and right cerebral hemispheres. Several human studies have revealed alterations in the structure of the corpus callosum in offspring following their exposure to maternal cigarette use during pregnancy (Jacobsen et al. 2007b; Paus et al. 2008). In animal models, prenatal exposure to nicotine has been shown to result in widespread alterations in gene expression in the brains of adolescent offspring (Cao et al. 2011, 2013; Wei et al. 2011). In particular, the expression of a number of genes involved in myelination—the formation of white matter via the addition of protective myelin sheaths to axons—is altered in a sex-dependent manner, with upregulation in males and downregulation in females (Cao et al. 2013). Such changes in the expression profiles of myelin-related genes may influence the structure and function of white matter, and both hypermyelination and hypomyelination have been associated with cognitive deficits (Quaranta et al. 2002; Sokolov 2007).

Deficits in Auditory Processing

A number of human studies, using a variety of methods, have investigated the effects of maternal cigarette smoking during pregnancy on auditory processing from the fetal period through childhood (Jacobson and Morehouse 1984; Kristjansson et al. 1989; McCartney et al. 1994; Franco et al. 1999; Leech et al. 1999; Cowperthwaite et al. 2007). Deficits in auditory processing in fetuses are of concern because they affect later language development (Kisilevsky and Davies 2007; Kisilevsky et al. 2014). Various studies in infants have investigated the brain's physiological activity response to auditory stimuli (the cochlea translates sound into nerve impulses to be sent to the brain), neuroelectric activity of the auditory nerve, and cochlear response (Key et al. 2007; Korres et al. 2007; Kable et al. 2009; Peck et al. 2010; Katbamna et al. 2013). Key and colleagues (2007) reported prenatal exposure to cigarette use (compared with nonexposed infants) to be associated with alterations in hemispheric asymmetry and suboptimal brain activity related to speech processing in otherwise healthy newborns at least 2 days of age. Korres and associates (2007) found altered cochlear responses to auditory stimuli in newborns that were exposed to maternal cigarette smoking (n = 200) compared with those that were unexposed (n = 200), regardless of degree of cigarette exposure. Similar findings were reported by Durante and colleagues (2011) in two case-control studies.

Two additional studies investigated effects of maternal cigarette use during pregnancy on auditory brainstem responses in newborns (≤ 2 days old) (Peck et al. 2010) and infants (6 months old) (Kable et al. 2009). Both studies found greater neuroelectric response to sound stimuli, a phenomenon that may disrupt an infant's ability to encode auditory information, potentially leading to deficits in language development. Furthermore, both studies demonstrated dose-response relationships between altered auditory processing and maternal cotinine levels. Finally, in a study of a small sample of newborns that sought to understand the direct biological pathway, maternal smoking during pregnancy produced changes in newborn cochlear and auditory brainstem functions and changes in placental gene expression in genes that appear to modulate the motility of cochlear hair cells (Katbamna et al. 2013). Thus, all three studies indicate effects based on consumption of conventional cigarettes, and they highlight the possibility of a mediating role of maternal nicotine use in altered infant

auditory processing, although further work must rule out confounding effects and effect modification by other constituents (e.g., arsenic, benzene, and cadmium).

A study using functional magnetic resonance imaging (fMRI) in older offspring exposed to tobacco in utero assessed response to auditory and visual attention tasks in adolescent smokers (Jacobsen et al. 2007a). Teens whose mothers smoked during pregnancy exhibited decreased accuracy in the tasks, with greater activation of both the temporal lobe and the occipital lobe, regions of the brain that are critical for auditory and visual processing. Additive effects of maternal cigarette use during pregnancy and of adolescent smoking on activation of the temporal and occipital lobes also emerged, indicative of reduced coordination among brain regions during auditory attention tasks.

Animal studies have shown that nAChRs play a critical developmental role in establishing synaptic connections between sensory thalamic afferents and those cortical targets that are necessary for normal sensory processing (Table A3.1-5 in Appendix 3.1). Brief nicotine exposure during this critical postnatal period of sensory cortex development disrupts glutamate transmission (Aramakis et al. 2000) and eliminates nAChR regulation of signal processing in the adult auditory cortex, inhibiting normal auditory learning (Liang et al. 2006). Animals that are prenatally exposed to nicotine also exhibit deficits in cognitive processing in response to an auditory cue, which appears to be mediated by a loss of function of the nAChR $\beta 2$ subunit (Liang et al. 2006; Horst et al. 2012).

Appetitive and Consummatory Behaviors

Clinical studies and animal studies have linked prenatal exposure to nicotine to subsequent appetitive behaviors (an active searching process that is performed consciously) and consummatory behaviors (such as ingestion of food or drugs) in offspring. Associations have been demonstrated in humans between maternal cigarette use during pregnancy and risk to the child of smoking uptake/nicotine dependence, drug abuse, and obesity; parallel relationships have been shown in animal models between prenatal exposure to nicotine and similar appetitive behaviors of offspring.

Parental use of tobacco is one of many well-known risk factors for offspring initiation of tobacco, progression to heavy use, and nicotine dependence. Tobacco use by parents influences their children through social, environmental, cognitive, and genetic mechanisms (USDHHS 2012). As a subset of these influences, mothers' use of tobacco during pregnancy has been studied as an independent risk factor and has been associated with offspring susceptibility, initiation, regular use, and dependence (Kandel et al. 1994; Griesler et al. 1998; Kandel and Udry 1999; Buka et al. 2003; Lieb et al. 2003; Oncken et al. 2004; Al Mamun et al. 2006; O'Callaghan et al. 2009; Tehranifar et al. 2009; Agrawal et al. 2010; Rydell et al. 2012; Weden and Miles 2012; Stroud et al. 2014; Shenassa et al. 2015). Wakschlag and colleagues (2010, 2011) suggest that maternal smoking during pregnancy has a teratologic effect with abnormalities stemming from the in utero environment which disrupt neural (Kandel et al. 1994; Jacobsen et al. 2006) and dopamine systems that promote sensitivity to nicotine dependence (Kandel et al. 1994; Selya et al. 2013). For example, nicotinic receptors of laboratory animals exposed to nicotine in utero are upregulated, suggesting a latent vulnerability to nicotine dependence among animals exposed to nicotine in utero (Slotkin et al. 2006, 2015).

At issue with all human studies investigating maternal use of tobacco during pregnancy and offspring use of tobacco is isolating the independent effect on the fetus in relation to the

other social, environmental, and cognitive factors that also predict offspring tobacco use. After controlling for maternal smoking during the offspring's childhood, several studies have reported that maternal smoking during pregnancy is associated with higher nicotine dependence in offspring (Kardia et al. 2003; Lieb et al. 2003; Selya et al. 2013; Shenassa et al. 2015), increased or earlier smoking initiation, and heavier smoking among adolescent girls and adult offspring (Kandel et al. 1994; Cornelius et al. 2005). However, the association was attenuated and nonsignificant among several studies that controlled for a variety of environmental, social, and cognitive confounders between maternal cigarette use during pregnancy and initiation of offspring smoking (but not nicotine dependence) (Cornelius et al. 2005; Roberts et al. 2005; Munafo et al. 2006; Kandel et al. 2007; D'Onofrio et al. 2012; Rydell et al. 2014; Taylor et al. 2014), leaving speculation for the independent effect. In summary, evidence from animal models offers a biologic mechanism for, and human evidence is suggestive of, an association between maternal tobacco use during pregnancy with offspring smoking and nicotine dependence, but is insufficient to infer causation. Further research and longitudinal studies that examine these outcomes while assessing the full spectrum of environmental, social, and cognitive mediating pathways are needed to disentangle these issues.

A smaller set of literature has documented associations between maternal cigarette smoking during pregnancy and use of other substances by the child (Fergusson et al. 1998; Weissman et al. 1999; Porath and Fried 2005; Nomura et al. 2011). In utero exposure to nicotine also affects behavioral responses for drug rewards in both adolescent and adult experimental animals. Prenatal exposure to nicotine increases the preference of adolescents for a saccharin solution containing nicotine compared with saccharin alone (Klein et al. 2003), and it results in self-administration of nicotine either during acquisition of the task (Chistyakov et al. 2010) or after forced abstinence (Levin et al. 2006). Prenatal exposure to nicotine also increases subsequent oral intake of alcohol (Chang et al. 2013), and intravenous self-administration of both cocaine and methamphetamine is enhanced in a dose-dependent manner in adolescent rats (Franke et al. 2008) and adult rats (Lacy et al. 2014).

In contrast, in a study that used a discordant sibling pair design to reduce confounding by genetic and environmental factors, initial associations between prenatal smoking and alcohol use disorder were attenuated and were no longer statistically significant (D'Onofrio et al. 2012). In a large longitudinal study that spanned 40 years, Shenassa and colleagues (2015) found evidence to support effects on nicotine dependence among children of mothers who smoked during pregnancy, but no effects on their progression to marijuana dependence were observed. A possible explanation for these discordant findings is suggested by a study that found significant effects from prenatal smoking of conventional cigarettes on drug use among adolescents, but showed that these effects were restricted to a genetic subpopulation of carriers of a specific $\alpha 6$ nAChR gene (*rs2304297*) polymorphism (Lotfipour et al. 2010). In sum, a number of studies have documented associations between cigarette use by the mother during pregnancy and smoking initiation, heavy use, and nicotine dependence among her children, although control of confounding reduces this association. In addition, the literature is sparse and inconsistent regarding a connection between maternal cigarette use during pregnancy and the use of nontobacco substances by the child.

A large body of literature has demonstrated effects of maternal cigarette use during pregnancy on weight levels and obesity in childhood. For example, three meta-analytic reviews found a 47–64% increased risk of obesity in children following exposure to maternal

cigarette smoking during pregnancy (Oken et al. 2008; Ino 2010; Weng et al. 2012; Behl et al. 2013). Additional systematic reviews (Bruin et al. 2010) and other studies (Harrod et al. 2015; La Merrill et al. 2015; Mourtakos et al. 2015; Bao et al. 2016) have all concluded that prenatal exposure to nicotine likely acts as a developmental obesogen in humans. However, unmeasured residual confounding or confounding by familial factors, which have not been fully explored, could attenuate the observed associations (Gilman et al. 2008; Iliadou et al. 2010). Animal studies support the epidemiologic literature suggesting a potentially causal relationship here by defining biologic pathways (Wong et al. 2015). Fetal and neonatal exposure to nicotine in rodents has resulted in neurochemical, neurobehavioral, and metabolic changes in the children that are consistent with obesity and type 2 diabetes (Williams and Kanagasabai 1984; Newman et al. 1999; Grove et al. 2001; Chen and Kelly 2005; Gao et al. 2005; Holloway et al. 2005).

In humans, studies involving structural MRI and fMRI have shown alterations in the size and sensitivity of brain reward centers in the teenage offspring of maternal smokers. Several of these studies revealed a thinning of the orbitofrontal cortex among persons who were prenatally exposed to maternal cigarette smoking, a thinning that was associated with drug use and experimentation during adolescence (Toro et al. 2008; Lotfipour et al. 2009); decreased amygdalar volume, which is associated with increased fat intake (Haghighi et al. 2013); and altered response to reward anticipation in the ventral striatum, an area associated with risk taking and drug use (Muller et al. 2013). In addition, highlighting the role of altered nicotinic pathways in the disruption of neural circuits from prenatal tobacco exposure, changes in striatal volume, and a propensity for drug use in adolescent offspring have been linked to interactions between prenatal exposure to cigarette smoking and a polymorphism in the gene encoding the $\alpha 6$ nAChR (Lotfipour et al. 2010). Structural alterations in the orbital frontal cortex have also been shown to result from interactions between maternal cigarette smoking during pregnancy and polymorphisms of brain-derived neurotrophic factor, a growth factor that regulates growth and differentiation of new neurons and supports existing neurons (Lotfipour et al. 2009). Although these clinical findings are specific to conventional cigarettes, they converge with results of animal studies of the effects of prenatal nicotine on brain reward centers and thus highlight the potential pernicious effects of e-cigarettes in pregnant women.

Animal studies have shown that the dopamine system, which is critically involved in satisfaction-seeking or appetitive behaviors, is modulated by nAChRs from the fetal period to adulthood (Azam et al. 2007). Prenatal nicotine exposure alters dopamine's content, turnover, release, and receptor expression in forebrain regions, which are important for motor and cognitive functions (Navarro et al. 1988; Richardson and Tizabi 1994; Muneoka et al. 1999; Zhu et al. 2012) and for assigning motivational value to natural and drug rewards (Kohlmeier 2015; McNair and Kohlmeier 2015). Prenatal exposure to nicotine also modifies the structure of dendritic targets of dopamine innervations in the nucleus accumbens (a critical component of reward learning and addiction) (Mychasiuk et al. 2013) and alters neuronal signaling that affects dopamine function (Chang et al. 2013; Morgan et al. 2013).

Prenatal exposure to nicotine has been shown in a variety of animal studies to induce complex effects on behavioral response to natural rewards. Although adolescent offspring of nicotine-exposed mothers show an initial decrease in motivation to work for sucrose reward (Franke et al. 2008), they exhibit enhanced sensitivity to the rewarding effects as the task

becomes harder (Lacy et al. 2012). Prenatal exposure to nicotine also results in enhanced intake of fatty foods, with no change in the intake of normal chow (Chang et al. 2013).

Attention and Cognition

Numerous human studies have investigated the effects of maternal cigarette use during pregnancy on disruptive behavior and attention deficits in the child. The 2014 Surgeon General's report included results of a systematic review of effects of maternal cigarette use during pregnancy on disruptive-behavior disorders—including ADHD, conduct disorder, and ODD—in offspring (USDHHS 2014). The evidence for effects of maternal cigarette use during pregnancy on disruptive-behavior disorders, and ADHD in particular, was suggestive but not sufficient to infer a causal relationship. Several systematic reviews using meta-analyses have found evidence for associations between exposure to maternal cigarette use during pregnancy and ADHD in offspring, including dose-response relationships between number of cigarettes smoked per day and ADHD symptoms (Linnet et al. 2003; Langley et al. 2005; Latimer et al. 2012; Massey et al. 2016). However, similar to effects on nicotine dependence and obesity in offspring, the possibility of unmeasured confounding remains (D'Onofrio et al. 2008; Thapar et al. 2009; Langley et al. 2012). Evidence for associations with maternal cigarette use during pregnancy is perhaps more consistent for offspring conduct disorders than it is for ADHD. In particular, although some studies that used a gene-environment interaction design or a propensity score-matching approach to exposure to control for confounding, they found no effect of maternal cigarette smoking during pregnancy on conduct disorders (D'Onofrio et al. 2008; Gilman et al. 2008; Boutwell and Beaver 2010; Lavigne et al. 2011). However, several other studies—including a meta-analytic review across three studies using “genetically sensitive”⁴ research designs—have suggested a direct causal relationship between maternal smoking during pregnancy and conduct disorders in offspring (McCrory and Layte 2012; Gaysina et al. 2013; Kuja-Halkola et al. 2014; Estabrook et al. 2015; Paus and Pausova 2015).

To explore the potential role of nicotine exposure in these associations, a small number of studies have included a prospective measure of confirmed tobacco exposure, maternal cotinine levels, in addition to maternal report of smoking, to study relationships with disruptive behaviors among offspring (Wakschlag et al. 2011; O'Brien et al. 2013; Massey et al. 2016). Wakschlag and colleagues (2011) found associations between maternal cigarette smoking and aggression and noncompliance among offspring. Studies have also shown alterations in the structure and function of the orbital frontal cortex, a region important for emotional regulation and cognition, in relation to maternal cigarette smoking during pregnancy (Toro et al. 2008; Bennett et al. 2009). Consistent with animal models of altered dopamine regulation, two studies have shown interactions of maternal cigarette smoking during pregnancy with dopamine regulation genotype (DAT1) in influencing disruptive-behavior phenotypes in offspring (Wakschlag et al. 2011; O'Brien et al. 2013). In another study, Wakschlag and colleagues (2010) demonstrated a sex-dependent interaction of maternal smoking during pregnancy with monoamine oxidase A (MAOA) genotype, which is associated with the development of antisocial behavior. In this study, maternal smoking

⁴ Genetically sensitive designs typically include monozygotic and dizygotic twins and a broader inclusion of sibling pairs, mother-child pairs, and grandparent-grandchild pairs. Genetically sensitive multigroup designs allow for simultaneous testing of additive and nonadditive genetic, common, and specific environmental effects, including cultural transmission and twin-specific environmental influences.

during pregnancy further increased the risk for conduct disorder. In sum, although issues of confounding remain, much evidence from human studies is suggestive of a causal association between maternal cigarette smoking during pregnancy and disruptive behaviors among offspring. This was confirmed by the 2014 Surgeon General's report on tobacco (USDHHS 2014). Since then, newer studies, controlling for personal and genetic confounders, have reported significant associations as well as nonsignificant, attenuated associations. Biologic evidence of nicotine-induced alterations in dopamine regulation also provides a possible mechanism for the role of nicotine in these outcomes.

Animal studies have shown that cholinergic modulation of prefrontal cortex function, via nAChRs, is essential for attention and cognition (Poorthuis and Mansvelder 2013; Proulx et al. 2014). Prenatal exposure to nicotine alters the morphology and nAChR functional response of prefrontal cortical neurons (Mychasiuk et al. 2013; Bailey et al. 2014). When tested as adolescents, animals that were exposed prenatally to nicotine show some behaviors characteristic of ADHD. For example, exposed offspring were found in two studies to show less impulse control and/or slower learning acquisition on two cognitive tests that tax attentional processes (Sorenson et al. 1991; Schneider et al. 2012). In addition, some studies have found hyperactivity in exposed offspring (Pauly et al. 2004; Schneider et al. 2012; Zhu et al. 2012), which was found in another study to be transmitted via maternal lineage from one generation to the next and to be ameliorated by methylphenidate treatment across all generations, showcasing the long-term impact of prenatal nicotine exposure (Zhu et al. 2014a). This transgenerational transmission of prenatal nicotine-induced hyperactivity must reflect longterm changes to the epigenome (Leslie 2013). Finally, emerging animal studies suggest that prenatal exposure to nicotine affects the proliferation and maturation of progenitor cells to glutamatergic neurons during neurodevelopment in the medial prefrontal cortex, resulting in behavioral impairments in attentional function and behavioral flexibility in adulthood (Aoyama et al. 2016; Poon and Leibowitz 2016; Powell et al. 2016).

Summary

Because of the rising prevalence of e-cigarette use, there is potential for widespread nicotine exposure to youth and young adults, resulting in nicotine addiction and related harmful consequences associated with exposure to nicotine. During pregnancy, there is neural sensitivity to the number and volume of substances, including nicotine, transported through the placenta. From prenatal development through adolescence and early adulthood, exposure to nicotine poses a serious threat, because these are critical times for brain development and brain plasticity. Furthermore, youth and young adults are more vulnerable than adults to the long-term consequences of nicotine exposure, including susceptibility to nicotine addiction and potentially reduced impulse control, deficits in attention and cognition, and mood disorders. An additional public health concern is exposure to e-cigarettes among persons who have never used conventional tobacco products. If the prevalence of e-cigarette use continues to rise among those who do not use conventional tobacco products, the harmful consequences of exposure to nicotine will rise accordingly.

The 2014 Surgeon General's report (USDHHS 2014) states there is sufficient evidence to infer that: (a) nicotine activates multiple biological pathways through which smoking increases risk for disease; (b) nicotine exposure during fetal development, a critical window for brain development, has lasting adverse consequences for brain development; (c) nicotine adversely affects maternal and fetal health during pregnancy, contributing to multiple adverse

outcomes such as preterm delivery and stillbirth; and (d) nicotine exposure during adolescence, a critical window for brain development, may have lasting adverse consequences for brain development and cognition. The literature presented in this section attempts to differentiate the risks to fetal and child health associated with nicotine in tobacco versus nicotine alone or in e-cigarettes. Evidence is sufficient to conclude tobacco use increases the risk of SIDS (USDHHS 2014), but further research is necessary with regard to nicotine alone or nicotine in e-cigarettes. The review finds evidence that tobacco is associated with structural brain changes and alterations in cognition, attention, and appetitive behaviors in human offspring. Less well known is the role that nicotine plays in mediating these associations, although animal models provide support for a role for nicotine in these outcomes. nAChRs, the chief receptor targets for nicotine, are widely expressed in the fetal brain, and their normal functioning is negatively affected by smoking and, in animals, by prenatal exposure to nicotine through experimental treatment. Furthermore, both human genetic studies and animal studies implicate a neurotoxic effect of fetal nicotine exposure. Pregnant women and women intending to become pregnant should be cautioned against using e-cigarettes to avoid unnecessary nicotine exposure to their baby.

Effects of the Inhalation of Aerosol Constituents Other Than Nicotine

The scientific literature on the health effects of exposure to constituents other than nicotine in the e-cigarette aerosol is still developing. One study found that after 5 minutes of ad lib e-cigarette use, healthy adult cigarette smokers showed an increase in airway resistance, but no effect on other spirometry parameters such as forced vital capacity (FVC), forced expiratory volume in 1 second FEV1, and ratios of these values (FEV1/FVC) (Vardavas et al. 2012).

A noninvasive marker of airway inflammation is the fraction of exhaled nitric oxide (FeNO) (Taylor et al. 2006; Munakata 2012). NO is a gaseous molecule that produces vasodilation and bronchodilation (decreasing resistance in the respiratory airway and increasing airflow to the lungs). FeNO is reduced by acute and chronic cigarette smoking (resulting in poorer vasodilation and bronchodilation) and is increased among smokers following cessation (see Vleeming et al. 2002 for a review). Studies examining current adult cigarette smokers revealed a reduction in FeNO after use of an e-cigarette with and without nicotine (Vardavas et al. 2012; Marini et al. 2014; Ferrari et al. 2015). One study found that these reductions did not differ significantly between e-cigarettes containing nicotine and those without nicotine (Marini et al. 2014), suggesting non-nicotine factors mediated the effect.

However, a study of occasional smokers (<10 cigarettes per week), but non-e-cigarette users, found an increase in FeNO after use of an e-cigarette containing nicotine (Schober et al. 2014). Furthermore, this study found no statistical difference in FeNO after use of an e-cigarette not containing nicotine. This variation in findings suggests the impact of e-cigarette use on FeNO may vary based on smoking history, nicotine content of e-liquid, or other environmental or biological factors.

Limited studies have examined chronic exposure on the potential inhalation toxicity of PG and VG. Prior to e-cigarettes, consumer products containing these chemicals were almost exclusively liquids or creams, or the substance was contained in a matrix. Animal models have shown few toxicological effects resulting from nose-only exposure to VG aerosol, with the exception of minimal or mild squamous metaplasia in rats exposed to the highest concentration (0.662 mg glycerol) for 13 weeks (Anderson et al. 1950; Renne et al. 1992).

Other inhalation studies testing PG in rats and monkeys did not observe treatment-related effects on respiratory physiology, clinical chemistry, hematology, gross pathology, or respiratory tract histology (Robertson et al. 1947). However, neither of these studies examined potential inhalation toxicity of PG and VG in humans using e-cigarette devices. In summary, other than nicotine, very little is known from human studies about the long-term health effects of inhaling PG and VG from e-cigarette aerosol, although adverse effects have been detected in animal models. Further investigation would improve our understanding of the effects of nicotine-related compounds, aerosolized solvents (PG and VG), aerosolized flavorants, aerosolized adulterants in e-liquids, and toxicants produced during the aerosolization process—or a combination of these chemicals.

Aerosolized Nicotine-Related Compounds

The nicotine used in e-liquids is extracted from tobacco. The extraction process may produce some potentially harmful tobacco-specific impurities, including minor alkaloids like nornicotine, anatabine, anabasine, myosmine, cotinine, nicotine-N-oxides (cis and trans isomers), β -nicotyrine, and β -nornicotyrine (Etter et al. 2013; Farsalinos et al. 2015a; Lisko et al. 2015; Oh and Shin 2015).

The correlation between nicotine and the concentrations of minor alkaloids is much stronger in conventional tobacco products (Jacob et al. 1999) than in e-cigarettes (Lisko et al. 2015). While the cause of these differing concentrations of minor alkaloids is unknown, Lisko and colleagues (2015) speculated potential reasons may derive from the e-liquid extraction process (i.e., purification and manufacturing) used to obtain nicotine from tobacco, as well as poor quality control of e-liquid products.

The American E-Liquid Manufacturing Standards Association (2014), an industry group with no regulatory authority, has called for the use of U.S. Pharmacopeia (USP)-grade nicotine in its e-cigarette products. USP specifications for nicotine allow for a maximum of 0.5% (5 mg/g) of a single impurity and 1% (10 mg/g) of total impurities (U.S. Pharmacopeia n.d.). Although the health implications of nicotine-related impurities are not known, toxicology studies are needed to demonstrate the effects of high levels of these products.

Aerosolized Solvents

Although e-cigarettes produce PG aerosols at levels known to cause eye and respiratory irritation to both users and nonusers (Offermann 2015), only mild effects (e.g., upper respiratory irritation) have been described in humans exposed to PG mist for 1 minute (Wieslander et al. 2001), and little is known about long-term effects. Inhaling PG can increase the risk of developing asthma (Choi et al. 2010). Animal studies of PG and VG aerosolizing agents not produced by e-cigarettes concluded that these substances are relatively safe when inhaled by animals for up to 28 days (Werley et al. 2011) or 18 months (Robertson et al. 1947).

Particles emitted from e-cigarettes are assumed to be formed from supersaturated PG (i.e., concentration beyond the point of saturation) in e-liquids (Schripp et al. 2013). Several studies designed to characterize the aerosol generated by e-cigarettes examined the chemical composition of the particles and their concentrations as measured by their number and distribution by size (Trehy et al. 2011; Ingebrethsen et al. 2012; Schripp et al. 2013; Zhang et al. 2013; Fuoco et al. 2014; Ruprecht et al. 2014; Saffari et al. 2014; Mikheev et al. 2016). E-cigarettes are recognized as a new source of submicron-sized particles, leading to possible

high exposure to these particles in users. Concentrations in the range of 10^9 particles $\times$ cm⁻³ were measured in the mainstream of e-cigarette aerosols (Fuoco et al. 2014). An in vitro study by Zhang and colleagues (2013) found that under the conditions of a single-puff experiment, an e-cigarette generated an aerosol having particle sizes in the range of 100–600 nm (nanometers), similar to that of conventional cigarettes. Mikheev and colleagues (2016) reported that the size distribution of e-cigarette aerosol differs from that of combustible tobacco smoke and that e-cigarettes normally exhibit a bimodal particle size distribution: nanoparticles (11–25 nm count median diameter) and submicron particles (96–175 nm count median diameter). Each mode has comparable number concentrations (107–108 particles/cm³). Goel and colleagues (2015) detected radicals in aerosols from all e-cigarettes and e-liquids tested ($2.5\text{--}10.3 \times 10^{13}$ radicals per puff at 3.3 V [voltage]), from e-liquid solvents PG and VG, and from “dry puffing” (overheating of e-liquid) (Farsalinos et al. 2015c).

Because the aerosols deriving from e-liquids are mainly made of droplets that are expected to dissolve as they reach the lung’s epithelium, not only the number but also the volume (size) of particles needs to be considered. Manigrasso and colleagues (2015) found that e-cigarettes are a source of extremely high doses of particles in the human respiratory system. On average, 6.25×10^{10} particles were deposited in the respiratory tree after a single 2-second puff, an estimated 30% of the daily doses of particles for a nonsmoking person. After 10 puffs, the relevant mean-layer thickness of the e-liquid on the lung epithelium was comparable to the thickness of surfactant layer covering the alveolar and bronchial regions, suggesting a higher susceptibility to irritant endpoints (Manigrasso et al. 2015). These results demonstrate that e-cigarettes produce submicron-sized particles and highly oxidizing free radicals that may present a potential toxicologic risk to e-cigarette users.

Aerosolized Flavorants

Little is known about the flavorants used in e-cigarettes, and more than 7,700 unique flavors are on the market (Zhu et al. 2014b). Flavored e-cigarette products are popular with adult users, and sweet and candylike flavors may make these products attractive to children and adolescents (Villanti et al. 2013; Farley et al. 2014; King et al. 2014). Many of the chemicals used in e-liquid flavorings are “generally recognized as safe” for ingesting (e.g., in food). However, these substances have not been tested adequately for safety when heated at various temperatures when inhaled in aerosolized form (Barrington-Trimis et al. 2014). The Flavor and Extract Manufacturers Association of the United States (2015), in an official statement, notes that ingredients in flavors are evaluated for exposure through ingestion only; thus, any results cannot be extrapolated to use through inhalation. Further, flavoring compounds often remain undeclared on e-cigarette and e-liquid packaging (Tierney et al. 2016).

CDC tested 36 e-cigarette products for 10 flavor compounds commonly used as additives in tobacco products (Lisko et al. 2015). Measurable levels of eucalyptol and pulegone were found in the menthol-flavored varieties for all manufacturers. Menthol concentrations ranged from 3,700 to 12,000 μ g/g in flavored e-liquids, levels similar to those found in the filler of conventional cigarettes. Interestingly, menthol was found at low concentrations in 40% of the tobacco-flavored nonmenthol products tested. Other flavor compounds found were camphor, methyl, salicylate, pulegone, cinnamaldehyde (CAD), and eugenol (Lisko et al. 2015).

Tierney and colleagues (2016) analyzed 30 e-cigarette products on the U.S. market and found 13 products contained more than 1% flavor chemicals by weight. Among the chemicals identified were aldehydes (e.g., benzaldehyde and vanillin), which are categorized as primary irritants of the respiratory tract (Roberts et al. 2015). Tierney and colleagues (2016) also found that tobacco-flavored e-liquids were derived from confection-flavored chemicals (e.g., bubble gum and cotton candy flavoring) rather than tobacco extract.

Some chemicals in e-cigarettes, although approved for ingestion, have established adverse health effects when inhaled. In vitro studies of cytotoxicity suggest that different flavored e-cigarette products may vary in their potential to adversely affect health. Bahl and colleagues (2012) reported cytotoxic effects of the solutions used in e-cigarettes that were not attributable to the nicotine but to the concentration of chemicals employed as flavors. These effects were most pronounced on mouse neural stem cells and human embryonic stem cells compared to human pulmonary fibroblast (Bahl et al. 2012).

Similar findings were reported by Behar and colleagues (2014) who found a greater cytotoxic effect of flavored e-liquid solutions on human embryonic stem cells compared to human pulmonary fibroblast. Further, two cinnamon-related chemicals, CAD and 2-methoxycinnamaldehyde, were particularly cytotoxic at doses found in the refill liquids (Behar et al. 2014). CAD, which is derived from the essential oil of cinnamon bark, is a highly bioactive compound (Jayaprakasha and Rao 2011). It has been used as an anticancer agent (Nagle et al. 2012), an insecticide (Cheng et al. 2009), and a bactericide (Nostro et al. 2012), and it is employed commercially as an additive in many foods and fragrances (Cocchiara et al. 2005).

Farsalinos and colleagues (2014a) analyzed 159 e-liquids obtained from a variety of manufacturers and retailers in Europe and the United States for the presence of two flavorings: diacetyl (DA) and acetyl propionyl (AP). The study revealed that these substances were present in the majority of the samples tested, with a significant proportion containing both chemicals. Furthermore, Allen and colleagues (2016) detected DA above the laboratory limit of detection in 39 of 51 flavors tested. DA, also known as 2, 3-butanedione, is a member of a general class of organic compounds referred to as diketones, α -diketones, or α -dicarbonyls. It provides a characteristic buttery flavor, is naturally found in various foods, and is used as a synthetic flavoring agent in food products such as butter, caramel, cocoa, coffee, dairy products, and alcoholic beverages. Although it is generally recognized as safe when ingested, it has been associated with a decline in respiratory function in persons exposed to it through inhalation (Egilman et al. 2011; Clark and Winter 2015). Inhaling DA and artificial butter-flavored powders and aerosols can cause fixed obstructive lung disease in exposed workers (Chaisson et al. 2010). In addition, it has been implicated in the development of bronchiolitis obliterans, an irreversible respiratory disease also called "popcorn lung disease" (Harber et al. 2006). AP, also called 2, 3-pentanedione, is a α -diketone that is chemically and structurally similar to DA. Although it has become a popular replacement for DA, acute inhalation exposure to AP has been shown to cause airway epithelial damage similar to DA (Hubbs et al. 2012).

The analysis by Farsalinos and colleagues (2014a) found that 74.2% of the sample contained one or both of these chemicals, with 69.2% of the sample containing DA. Both DA and AP were found in 28.3% of the sample e-liquids. These chemicals were detected even in samples coming from manufacturers that stated these flavorings were not present in their products. However, exposure to DA and AP was 100 and 10 times lower, respectively, than

exposure to these chemicals from cigarette smoking. Few studies have examined safe levels of DA and AP via tobacco product; however, 47.3% of DA- and 41.5% of AP-containing samples exposed consumers to levels higher than the safety limits outlined by the National Institute for Occupational Safety (NIOSH) for occupational exposure. This exposure threshold outlined by NIOSH is not intended to suggest exposure at or below that limit should be considered sufficiently safe (Hubbs et al. 2015).

Aerosolized Adulterants

TSNAs, potent carcinogens identified in tobacco and tobacco smoke, include N-nitrosornicotine (NNN), 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK), N-nitrosoanabasine (NAB), and N-nitrosoanatabine (NAT) (Hecht 1998, 1999; USDHHS 2010, 2014). NNN and NNK are classified by the International Agency for Research on Cancer (IARC) as Group 1 human carcinogens (IARC 2004). Their presence in e-liquids is mostly attributable to the processes used in extracting nicotine from tobacco leaves or the addition of tobacco flavorings (Kim and Shin 2013; Cheng 2014). These compounds are formed from their alkaloid precursors and from nitrite or nitrate, predominantly during tobacco curing, fermentation, and aging. NNN, NAB, and NAT are formed primarily from their corresponding secondary amines (nornicotine, anatabine, and anabasine) in the early stages of tobacco curing and processing, while the majority of NNK is formed from the tertiary amine nicotine at the later stages of tobacco curing and fermentation (Hecht 1998). Nitrosation reactions of corresponding amines can occur in e-liquids, especially during inadequate storage or manufacturing processes; inadequate storage is believed to increase the levels of NNN as a consequence of the nitrosation of nornicotine converted from nicotine in liquids (Kim and Shin 2013).

Some studies have identified traces of TSNAs in e-liquids, but at levels far below those seen in combustible tobacco (Trehly et al. 2011; Farsalinos et al. 2015a). Further, Goniewicz and colleagues (2014b) found that the aerosol of some e-cigarettes contains traces of the carcinogenic nitrosamines NNN and NNK, but neither was detected in aerosol from the Nicorette inhalator (an NRT product).

Several studies have reported the presence of other hazardous compounds in e-liquids or in the aerosol produced by e-cigarettes (Exponent Inc. 2009; Hadwiger et al. 2010; Lim and Shin 2013; Uchiyama et al. 2013; Williams et al. 2013; Bekki et al. 2014; Goniewicz et al. 2014a,b; Kosmider et al. 2014; Jensen et al. 2015; Kavvalakis et al. 2015; Laugesen 2015; Oh and Shin 2015; Varlet et al. 2015; Khlystov and Samburova 2016). For example, an FDA study detected the presence of amino-tadalafil and rimonabant in e-liquids (Hadwiger et al. 2010); amino-tadalafil is a structural analogue of tadalafil, the active pharmaceutical ingredient in Cialis, a prescription drug approved in the United States for treatment of erectile dysfunction. Rimonabant (trade name Zimulti) was approved in Europe for the treatment of obesity, but its marketing authorization was withdrawn by the European Medicines Agency in 2009. FDA approval of this drug has been withheld because of unresolved issues involving rimonabant therapy and increased frequencies of psychiatric adverse events, including suicide and an ill-defined constellation of neurologic symptoms and seizures (FDA 2007). The presence of unapproved active pharmaceutical ingredients suggests that some e-cigarettes may expose users to pharmacologically active substances with undocumented and unknown effects.

Oh and Shin (2015) conducted a study to identify and quantify the presence of diethyl phthalate (DEP) and diethylhexyl phthalate (DEHP) in e-liquids. DEP is used as a solvent to bind cosmetics and fragrances and in various industrial applications, including plasticizers, detergent bases, and aerosol sprays. DEHP is used widely as a plasticizer in the manufacture of articles made of polyvinylchloride. DEP and DEHP were detected in 47.6% and 79.1% of e-liquids, respectively, with concentration ranges of 0.01–1745.20 mg/L and 0.06–81.89 mg/L (Oh and Shin 2015). Both DEP and DEHP have estrogenic and antiandrogenic activity that cause premature breast development in girls. DEHP is classified by IARC as a possible carcinogen in humans (IARC 2000). Although the amounts of the two phthalates detected in this study were lower than the safety levels, the source of these toxicants is unknown, perhaps coming from packaging materials and the production procedure.

Carbonyls are present in e-cigarettes, and levels increase with device voltage (Kosmider et al. 2014; Jensen et al. 2015). Long-term exposure to carbonyl compounds, such as formaldehyde, acetaldehyde, and acrolein, increases the risk of cancer. IARC and the U.S. Environmental Protection Agency (EPA) have classified formaldehyde as “carcinogenic to humans” (USDHHS 1999; IARC 2009). EPA has set the acceptable daily intake (ADI) of formaldehyde as 0.2 mg/kg (kilograms) body weight and has warned of the potential adverse health effects of exceeding ADI. Acetaldehyde is also toxic, an irritant, and a probable carcinogen (USDHHS 1999). Acrolein is toxic through all routes of administration and may cause respiratory and ocular irritation (Faroon et al. 2008; Bein and Leikauf 2011). Acrolein in cigarette smoke has been linked to several pulmonary diseases, including increased risk of lung cancer (Feng et al. 2006), as well as asthma and chronic obstructive pulmonary disease (Bein and Leikauf 2011). One study found an association between acrolein exposure and risk of cardiovascular disease (DeJarnett et al. 2014).

Lim and Shin (2013) detected formaldehyde and acetaldehyde in 225 replacement liquids for e-cigarettes purchased in Korea, with ranges of 0.02–10.09 mg/L (mean 2.16 mg/L) and 0.10–15.63 mg/L (mean = 4.98 mg/L). Although the amounts of formaldehyde and acetaldehyde detected in replacement liquids for e-cigarettes are relatively low compared to conventional cigarettes, they should be controlled to the lowest possible concentrations in raw materials, as they may be formed when e-liquids are heated. Furthermore, as larger capacity batteries and heating mechanisms are developed (Farsalinos et al. 2014b; Sleiman et al. 2016), users will be exposed to higher concentrations of formaldehyde, acetaldehyde, acrolein, and other carbonyls (Kosmider et al. 2014). Jensen and colleagues (2015) reported formaldehyde concentrations higher than conventional cigarettes in high-voltage e-cigarettes. Havel and colleagues (2016) reported acetaldehyde, acrolein, and formaldehyde generation increased markedly at voltages at or above 5 volts. Geiss and colleagues (2016) reported that formaldehyde exceeded safety levels at the lowest wattage (5 watts), which is the wattage applied in most second generation e-cigarettes.

Summary

Although some typical constituents of the e-cigarette aerosol have been identified, the potential short- and long-term health consequences of inhalation of the heated and aerosolized constituents of the e-liquids, including solvents, flavorants, and toxicants, still require further investigation to quantify health effects. Commercial and custom-mixed e-liquids are produced with undisclosed manufacturing procedures, packaging materials, and purity standards for their constituents, increasing the risks of potential health consequences. E-cigarettes are a

source of extremely high doses of fine particles (e.g., aerosol) in the human respiratory system. Fine particles are emitted when the solvents PG and VG are aerosolized, and mild respiratory effects have been documented, but adequate assessments are lacking. An additional concern is the aerosolization and inhalation of flavor additives in e-liquids. While some of the chemicals used may be generally recognized as safe for use in foods, they have not been thoroughly tested for their potential sensitizing, toxic, or irritating characteristics when inhaled. Further, given the extent of possible variations in the ratio of flavor additives, with up to 7,700 unique e-liquid varieties available (Zhu et al. 2014b), these chemicals may be toxic in the concentrations present in manufactured or do-it-yourself e-liquids. Finally, other hazardous compounds and carcinogens have been detected in e-liquids, or in the heated aerosol produced by e-cigarettes, including formaldehyde, acetaldehyde, and acrolein.

Effects of Toxicants Produced during Aerosolization

A primary reason for investigating the health effects of heated and aerosolized e-liquids is that, under such conditions, chemical reactions may result in the formation of new compounds (Sleiman et al. 2016). In some devices, the temperature in the center of a heating coil can exceed 350°C, causing changes in the chemical components of the e-liquid. When carbonyl compounds are present in the refill liquids, heating can enhance their concentrations in the aerosol (Talib et al. 2015). Carbonyl compounds result from dehydration and fragmentation of VG and PG, which can be oxidized to formaldehyde and acetaldehyde during heating. Hutzler and colleagues (2014) applied headspace gas chromatography-mass spectrometry to enable incubation of liquids at various temperatures. At 150°C, the levels of acetaldehyde and formaldehyde were found to be up to 10-fold higher than they were at ambient temperatures for samples in which PG was a main component. The generation of carbonyl compounds seems to increase when liquids touch the heating element inside an e-cigarette, which is indicated by a color change around the wire, as has been reported in some devices (Uchiyama et al. 2013). Evidence suggests when e-liquid touches the heating element (heated nichrome wire), it is oxidized to formaldehyde, acetaldehyde, acrolein, glyoxal, and methylglyoxal in the presence of oxygen (Bekki et al. 2014; Goniewicz et al. 2014b; Kosmider et al. 2014).

Several studies have reported that short-chain aldehydes, such as formaldehyde, acetaldehyde, or acrolein, are produced during heating. Uchiyama and colleagues (2013) measured carbonyl compounds in e-cigarette aerosols generated according to the Canadian “intense regimen” (55mL puff volume, 2-second puff duration, 30 seconds between puffs, and a total of 10 puffs). Thirteen brands of e-cigarettes were assessed, and investigators detected several carbonyl compounds, such as formaldehyde, acetaldehyde, acetone, acrolein, propanol, crotonaldehyde, and butanol. They also detected two other harmful carbonyl compounds that had not been detected in the mainstream smoke from conventional cigarettes: glyoxal and methyl-glyoxal. Jensen and colleagues (2015) observed that formaldehyde-containing hemiacetals can be formed during the aerosolization process. These molecules are known to release formaldehyde and are used as industrial biocides, but it is not currently known how formaldehyde-releasing agents affect the respiratory tract.

The amount of carbonyl compounds in e-cigarette aerosols varies substantially, not only among different brands but also among different samples of the same products (Ohta et al. 2011; Bekki et al. 2014; Kosmider et al. 2014; Jensen et al. 2015), from 100-fold less than tobacco to nearly equivalent values. Notably, the amount of voltage the battery puts out

affects the concentration of the carbonyl compounds in the emission. Some e-cigarettes allow users to increase aerosol production and nicotine delivery by raising the battery's output voltage. In addition, some users elect to directly drip e-liquid onto an exposed heater coil, reportedly for greater aerosol production and "throat hit." Talih and colleagues (2015) showed that use of such direct-drip atomizers may involve greater exposure to toxic carbonyls, including formaldehyde, because of the potentially higher temperatures reached by the coil. The adverse effects of acrolein (2-propenal), an unsaturated aldehyde, depend on dose and cell type and are influenced by experimental conditions (Bein and Leikauf 2011). In vitro studies found that acrolein inhibits DNA repair and forms acrolein-deoxyguanosine DNA adducts that are mutagenic (Wang et al. 2009, 2012; Tang et al. 2011). Despite the known DNA-damaging effects of acrolein, its mutagenicity in mammalian cells remains uncertain, and according to an evaluation by the IARC, there is inadequate evidence for carcinogenicity in humans or animals (IARC 1995). Because of its extreme toxicity, acrolein has been difficult to characterize in standard animal carcinogenicity tests. Animal experiments showed that acrolein can have a range of adverse effects, including a role in carcinogenesis (Cohen et al. 1992); excessive mucus production and macrophage and neutrophil accumulation with consequent production of proinflammatory cytokines and proteases (Moretto et al. 2012); damage to neurons and myelin disruption (Shi et al. 2011); and it may play a role in the progression of atherosclerosis and cardiovascular disease (Park and Taniguchi 2008; DeJarnett et al. 2014).

Other volatile organic compounds (VOCs) found in e-cigarette aerosol include a variety of chemicals (e.g., aliphatic and aromatic hydrocarbons), some of which may have short- or long-term adverse health effects. Benzene (classified as group 1 by IARC) and other solvents (toluene, xylenes, and styrene) could be present in e-cigarettes because of their use in the extraction of nicotine from tobacco leaves. Goniewicz and colleagues (2014b) detected both toluene and m- and p-xylene in e-cigarette aerosols. A wide variety of other VOCs in e-cigarette liquids produce aromas and flavor through heating (Tierney et al. 2016).

Heavy metals such as tin, lead, and nickel were discovered by Williams and colleagues (2013) in a brand of e-liquids and the resulting aerosols. Those researchers analyzed the contents of e-cigarette cartomizers (a polyfill wrapped heating coil capable of longer puff durations than an atomizer) and the aerosols by using light and electron microscopy, x-ray microanalysis, particle counting, and inductively coupled plasma optical emission spectrometry. The aerosol contained particles $>1\ \mu\text{m}$ that were composed of tin, silver, iron, nickel, aluminum, and silicate, and nanoparticles ($<100\ \text{nm}$) of tin, chromium, and nickel. Small particles composed of various elements (tin, other metals, semimetals, and silicates) passed through the cartomizer fibers and were present in aerosols. These particles likely originated from parts of the device (i.e., atomizer/cartomizer) (Williams et al. 2013).

Concentrations of 9 of the 11 elements in e-cigarette aerosol identified by Williams and colleagues (2013) were higher than or equal to concentrations in conventional cigarette smoke. Many of the metals identified in e-cigarette aerosol, such as lead and cadmium (Farsalinos et al. 2015b), are known to cause respiratory distress and disease (Zalups and Ahmad 2003). These metals are produced by the aerosolization of e-liquids (Farsalinos et al. 2015b) and by flaws in e-cigarette heating mechanisms and poor quality control (Williams et al. 2013; Farsalinos et al. 2015b; Mikheev et al. 2016). While these initial analyses indicate potential exposures, additional measures are needed because of challenges in measuring trace levels of metals.

Summary

E-liquids produce chemical reactions that may result in the formation of new, harmful compounds. Carcinogens (e.g., formaldehyde, acetaldehyde, and acrolein) and toxic heavy metals (e.g., lead and cadmium) have been found in e-cigarette aerosols in laboratory tests conducted at temperatures within the range of most e-cigarette products. These chemicals and metals have been detected in e-liquids and e-cigarette aerosols, signifying the need for further study on the potential short- and long-term health ramifications.

A limitation to understanding the health impact of chemical reactions is the heterogeneity of e-cigarette devices (e.g., voltage), e-liquids (e.g., quality, content), and use behaviors (e.g., puff duration), as emissions may be altered by any combination of these mechanical and behavioral differences. Further, it is difficult to fully contextualize the carcinogenic emissions of e-cigarette aerosol given the diversity of products currently available, as well as those that may become available as the devices continue to evolve (Farsalinos et al. 2014b).

Effects Not Involving Inhalation of Aerosol by the E-Cigarette User

Health effects not attributable to direct inhalation of e-cigarette aerosol include explosion or fire associated with malfunctioned devices, poisoning through contact exposure or intentional or unintentional ingestion of e-liquid, and exposure to secondhand aerosol or its condensate.

Health Effects Attributable to Explosions and Fires Caused by E-Cigarettes

Most reports of explosions and fires caused by e-cigarettes have appeared in print and online media and on televised programs. From August 2009 to March 2014, a search of U.S. media by the U.S. Fire Administration (2014) found 25 reports of e-cigarette explosions or fires. These data suggest that the number of such events is small when compared with the number of e-cigarette users. Of the 25 incidents found in the search, 2 caused serious harm, and there were no deaths attributable to explosions. In most cases, the resulting fires did not spread far from the site of the explosion. However, in one case an entire bedroom was lost to fire (U.S. Fire Administration 2014). As for explosions, several have occurred during an e-cigarette's use, causing severe facial damage or injuries to bodies and hands (Brennan 2015; Corona and Marcus 2015; Duranty 2015; Fox 5 Digital Team 2015; Goff and Schwartz 2015; Jablow and Sexton 2015; Shastry and Langdorf 2016), but most occurred while the device's batteries were being charged. Overcharging lithium batteries can lead to thermal runaway, causing the e-cigarette battery or container to be propelled, often with portions catching fire (U.S. Fire Administration 2014; Bohr et al. in press).

Health Effects Caused by Ingestion of E-Cigarette Liquids

The liquids in both e-cigarettes and the containers used to refill them can cause nicotine poisoning. Consequences of nicotine intoxication in the e-liquid include nausea, vomiting, headaches, dizziness, and diarrhea at low doses; seizures; tachycardia; abdominal pain; confusion; and even death (Cervellin et al. 2013). The amount of nicotine needed to cause death in humans is uncertain and, according to a reevaluation, may be higher than previously thought (Mayer 2014). The total amount of nicotine in refill liquids varies and can be as high as 1,000 mg/10 mL in do-it-yourself bottles (Davis et al. 2015), which could be lethal if consumed (Mayer 2014).

The increase in poisonings prompted enactment of the *Child Nicotine Poisoning Prevention Act of 2015* (2016) in January 2016. This law requires any container of liquid nicotine sold, manufactured, distributed, or imported into the United States be placed in special packaging that is difficult to open by children under 5 years of age. Although labels may indicate the concentrations of nicotine, such labels can be incomplete, confusing, or inaccurate (Tritchounian and Talbot 2011; Cameron et al. 2014), and some bottles have not been labeled at all (Davis et al. 2015). Of most concern, some bottles of e-cigarette refill liquids labeled “no nicotine” have been found to contain significant amounts of that substance (e.g., 25.6 mg/mL; Trehy et al. 2011). Regardless, many e-cigarette users may not be aware of the toxic effects of nicotine and may not know that refill liquids should be kept away from toddlers and children. These liquids are often sold in colorful bottles with flavors that are attractive to children (Bahl et al. 2012). The liquids usually come in small dropper bottles that can be mistaken for bottles containing food dye or eye drops. Finally, many refill liquids are made in local “vape shops,” which have only recently come under FDA regulation (*Federal Register* 2016), with no uniform training process for mixers, a lack of standards and protections, and unknown concentrations of nicotine.

The rapid growth in popularity of e-cigarettes and the ease with which refill liquids can be purchased have made e-cigarettes an increasingly common item in many households, thereby elevating the possibility of accidental nicotine poisoning. Instances of related case reports, often involving children or infants, are increasing. For example, an 18-month-old girl was treated at an emergency room for hypertension and tachycardia after drinking about 2 mL of refill liquid from a bottle on a nightstand (Shawn and Nelson 2013). Unintentional exposure to nicotine can occur through ingestion, absorption through the skin, inhalation, or dropping refill liquids into one’s eyes (Cantrell 2014).

Note: These numbers reflect the closed human exposures to e-cigarettes and liquid nicotine reported to poison centers as of July 31, 2016. The numbers may change as cases are closed and additional information is received.

Figure 3.2. Data showing exponential increase in the number of cases of human exposure to e-cigarette products and liquid nicotine between 2011 and 2016.

Figure 3.2 shows data from 2011 to 2016 on exposures to e-cigarettes or liquid nicotine (i.e., any contact with e-cigarettes or liquid nicotine, not necessarily resulting in any health effects) (American Association of Poison Control Centers 2016). These data show a dramatic increase in exposures through 2014 with a slight reduction of exposures in 2015. Fifty-one percent of the calls to poison control centers regarding exposures to e-cigarettes involved children 5 years of age or younger (CDC 2014). Increased e-cigarette exposures have also been reported by state and local poison centers (Banerji et al. 2014; Cantrell 2014; Guttentburg et al. 2014; Lee et al. 2014; California Department of Public Health 2015).

Secondhand Exposure to the Constituents of E-Cigarette Aerosol

Exposure to secondhand smoke from combustible tobacco products is a known cause of morbidity and mortality (USDHHS 2006). Secondhand smoke, a mixture of the sidestream smoke from a smoldering cigarette and the mainstream smoke exhaled by a smoker, is known to contaminate both indoor and outdoor environments. In addition, when the constituents of smoke deposit on surfaces, nonsmokers can be exposed to them via touch, ingestion, or inhalation. These deposited constituents of combustible smoke are known as “thirdhand smoke” (Matt et al. 2011; Protano and Vitali 2011). E-cigarettes represent another potential source of exposure to toxicants for nonusers, via secondhand or thirdhand exposure to aerosol.

Exposure to Nonusers

In contrast to combustible tobacco products, e-cigarettes do not produce sidestream emissions; aerosol is produced during activation of the device. Some of this aerosol is subsequently exhaled into the environment where nonusers may be exposed through inhalation, ingestion, or dermal contact. As previously described in this chapter, constituents of the emissions may include nicotine, carbonyl compounds, VOCs, polyaromatic hydrocarbons, TSNA, heavy metals, and glycols. It is not clear how much of inhaled e-cigarette aerosol is exhaled into the environment where nonusers can be exposed. Some studies have used machines to produce e-cigarette aerosols and measured the pollutants emitted (McAuley et al. 2012; Czogala et al. 2014; Geiss et al. 2015); others have involved the use by one or more persons of an e-cigarette and measured the change in pollutants in either a room or a test chamber after use (Schripp et al. 2013; Schober et al. 2014). One study measured airborne nicotine in the homes of e-cigarette users (Ballbe et al. 2014). The concentration of e-cigarette aerosol in a given microenvironment depends primarily on the strength of the source or the number of e-cigarettes used and the emission rate of the aerosol for that device. E-cigarettes, however, are heterogeneous in their design and in the liquids used, and the specific product combination significantly affects the secondhand emissions (Kosmider et al. 2014; Geiss et al. 2015). The number of puffs and depth of inhalation may be particularly relevant to the amount exhaled by the user and may also affect e-cigarette emissions (Talih et al. 2016).

Movement of E-Cigarette Aerosol

Similar to the case with secondhand tobacco smoke, e-cigarette aerosol is an inherently dynamic mixture that changes over time in terms of constituents and concentrations. Czogala and colleagues (2014) demonstrated a significant signal from a laser photometer indicating

the presence of ambient aerosol in a room after e-cigarette use. However, this aerosol disappeared in just seconds to a few minutes as it either evaporated to the gas phase or deposited on surfaces in the room. In contrast, in the same study, secondhand cigarette smoke exhibited a particulate phase that stayed suspended in the room at high concentrations for more than 30 minutes. For the VOCs in e-cigarette aerosol, such as formaldehyde, acrolein, and acetaldehyde, the source strength and ventilation rate will largely determine their concentration in indoor air. Semi-VOCs, such as nicotine and TSNAs, are also largely affected by sorption on and subsequent desorption from surfaces and dust in a room (Singer et al. 2002, 2003; Goniewicz and Lee 2015). The extent of this type of thirdhand contamination from e-cigarettes in real-world settings has not been established but would be of particular concern for children living in homes of e-cigarette users, as they spend more time indoors, are in proximity to and engage in greater activity in areas where dust collects and may be resuspended (e.g., carpets on the floor), and insert nonfood items in their mouths more frequently (EPA 2008; Matt et al. 2011).

Exposure to E-Cigarette Aerosol and Considerations of Dose

A large body of studies has measured exposure to secondhand and thirdhand smoke from conventional cigarettes using personal or area air monitoring, surface testing, and dust testing. Studies of the exposure of e-cigarette aerosol to nonusers, however, are limited. Schripp and colleagues (2013) observed small increases of fine and ultrafine particles and some VOCs, including PG, flavoring substances, and nicotine, indicating passive inhalation of e-cigarette aerosols by nonusers in the presence of e-cigarette users. Those authors demonstrated that the distribution in the sizes of the aerosol's component particles changes in the lungs and results in the exhalation of smaller particles, likely caused by the evaporation of the liquid particles in the lungs and in the environment after exhalation. Schober and colleagues (2014) found substantially higher amounts of PG, VG, particulate matter (PM), and nicotine in a 45-m³ chamber during e-cigarette use sessions with volunteers compared to controlled sessions. They also found a 20% increase in the level of polycyclic aromatic hydrocarbons (PAHs) and a 2.4-fold increase in aluminum concentrations.

Williams and colleagues (2013) demonstrated contamination by metal and silicate particles in e-liquid and its aerosol using scanning electron microscopy. In a different study measuring machine-generated secondhand e-cigarette aerosol in an emission chamber, Geiss and colleagues (2015) found significant levels of PG, VG, and nicotine in the chamber's air. Carbonyl compounds of concern (e.g., formaldehyde, acetaldehyde, acrolein, and acetone) were below the limits of detection in this study. O'Connell and colleagues (2015), who assessed secondhand e-cigarette emissions in a small meeting room (12.8 m²) with three e-cigarette users during a 165-minute session, found a significant increase in PG but did not see the expected increase in VG or nicotine. This study reported no increase in PAHs, trace metals, TSNAs, or acrolein, but did find an increase in total VOCs, formaldehyde, and acetaldehyde. However, the compounds were found at levels below guidelines for the quality of indoor air from the World Health Organization or European Union. Ruprecht and colleagues (2014) found significantly lower concentrations and counts for particles from an e-cigarette used in a 50-m³ room compared with conventional cigarettes. Interestingly, they also found that nicotine-free e-cigarettes produced higher particle levels than e-cigarettes containing nicotine. Saffari and colleagues (2014) found that total particulate exposure was 10-fold lower in e-cigarettes than it was in conventional cigarettes. Emissions of heavy metals

from e-cigarettes were also dramatically less, with the exception of nickel, zinc sulfide, and silver, which showed higher emission rates from e-cigarettes. PAH levels were not elevated by e-cigarette use in this study.

Concentrations of PM, especially PM_{2.5}, which is fine PM, and nicotine are the two most common markers used to measure exposure to secondhand smoke (Avila-Tang et al. 2010; Apelberg et al. 2013). Indirect measures of the mass concentration of PM from secondhand smoke using real-time particle monitors are well validated in terms of the accuracy of these measurements in relation to other constituents of secondhand smoke and to health effects (Hyland et al. 2008; Apelberg et al. 2013). These same types of particle monitors are often used in studies of e-cigarette aerosol to compare PM levels from conventional cigarettes with those from e-cigarettes, though PM findings may not directly relate to the short- and long-term health effects of each product (Czogala et al. 2014; Schober et al. 2014).

Caution is warranted when interpreting the results of PM measurements comparing e-cigarettes with conventional cigarettes. The aerosols produced are fundamentally different, with the former resulting from aerosolization of liquid and the latter resulting from combustion of organic matter. The true PM_{2.5} mass concentration of e-cigarette aerosol from commonly used light-scattering instruments (Czogala et al. 2014) cannot be determined without calibrating the device to a reference standard for the aerosol in question. Even this calibration would be questionable given the highly volatile nature of e-cigarette aerosol, making it difficult to capture and accurately determine the mass. Real-time PM_{2.5} measurements such as this are useful, however, to determine the presence of an aerosol and to see the *relative* changes in this aerosol over time and under various conditions, such as changing source strength. Figure 3.3 shows the significant increase in aerosol concentration from e-cigarettes after about 1 hour and the subsequent rapid decline, presumably from initial aerosolization and deposition of this aerosol. There may still be significant amounts of this e-cigarette aerosol in the environment, but the particle monitor can no longer measure it, as it is either in the aerosol phase or deposited on surfaces. For these reasons, it is important not to rely solely on PM mass concentrations for determining exposure to e-cigarette aerosol and for making comparisons with conventional cigarettes. Measurement of the individual toxicants of concern in the aerosol phase and on surfaces is warranted.

Health Effects of Secondhand Exposure to E-Cigarette Aerosols

Flouris and colleagues (2012, 2013) conducted two clinical studies of the health effects of secondhand exposure to e-cigarette aerosol. The researchers found no short-term change in markers of complete blood count after 1 hour of exposure to e-cigarette aerosol in a group of 15 nonsmokers (Flouris et al. 2012). Similarly, the same exposure caused no significant change in short-term lung function, although the results were of borderline statistical significance (Flouris et al. 2013). However, these studies demonstrated that passive exposure to e-cigarettes causes an increase in serum cotinine that is similar to that from passive exposure to cigarette smoke, suggesting the need to examine the impact of passive aerosolized nicotine inhalation on long-term lung function. Furthermore, limited effects would likely occur in the short exposure observed through the methodologies used by Flouris and colleagues (2012, 2013), as these studies did not account for prolonged and persistent passive exposure to e-cigarette aerosols.

Several researchers have modeled the health risks of passive exposure to e-cigarettes (Colard et al. 2015) on the basis of the limited exposure data available and have come to

various conclusions. Offermann (2015) concluded that, for indirect exposure, two chemicals—nicotine and PG—exceeded California EPA exposure level standards for noncarcinogenic health effects. Burstyn (2014), who compared e-cigarette aerosol exposure to workplace exposure standards, concluded that only PG and VG warrant attention in e-cigarette users while, for bystanders, none of the constituents of e-cigarette aerosol pose apparent concern. It is important to note that standards for workplace exposure are typically not appropriate to apply to the population as a whole, as they are intended for a healthy working population during a typical work day, not accounting for the risks to children, pregnant women, or those with preexisting health conditions. Further, standards for workplace exposure are very different in concentration and duration than what is to be expected from e-cigarette use.

Note: PM = particulate matter.

Figure 3.3. Changes in aerosol particle PM_{2.5} concentrations during experiment of e-cigarette use and tobacco cigarette smoking in an exposure chamber.

An additional consideration for regulating e-cigarettes in indoor environments is the potential for allergic reactions in nonusers. Dermal and oral PG exposures are known causes of dermatitis and allergic sensitization (Warshaw et al. 2009; Al Jasser et al. 2011). Several e-liquids contain flavorants derived from nuts and in fact have labels cautioning persons who have nut allergies not to use these products. Research has not evaluated whether nonusers can have allergic reactions from these potential allergens in e-cigarette aerosol, but this is a risk that should be explored as 8% of U.S. children have food allergies (Gupta et al. 2011).

Evidence Summary

E-cigarette use among youth and young adults in the United States has increased considerably in recent years (see Chapter 2). There is little doubt that the use of e-cigarettes by youth and young adults represents self-administration of the drug nicotine, and this self-administration of nicotine puts youth at risk for addiction and many related harmful consequences. Animal research indicates adolescent brains are particularly sensitive to

nicotine's effects, such that subsequent self-administration is more likely, and that same literature indicates that this age group is at risk for a constellation of nicotine-induced neural and behavioral alterations. Studies of the effects of maternal smoking of conventional cigarettes during pregnancy, coupled with preclinical literature examining the effects of maternal self-administration of nicotine during pregnancy, suggest that e-cigarette use by mothers during pregnancy presents a wide variety of risks to fetal, infant, and child brain development.

Users of e-cigarettes risk respiratory exposure to a variety of aerosolized chemicals, including solvents and flavorants added intentionally to e-liquids, adulterants added unintentionally, and other toxicants produced during the heating/aerosolization process. The health impacts of frequent exposure to the toxicants in e-cigarette aerosol are not well understood, though several are known carcinogens. As highlighted previously in this chapter, the detection and level of these carcinogens depend on several factors, including the concentration of the e-liquid and the strength of the heating device. Although e-cigarettes have been used as a cessation device, the evidence supporting the effectiveness of e-cigarettes as an aid for quitting conventional cigarettes remains extremely weak for adults (Bullen et al. 2013; Caponnetto et al. 2013; Grana et al. 2014; Kalkhoran and Glantz 2016) and untested and nonexistent among youth.

Further research is warranted to focus on the characteristics of e-cigarette devices, the constituents of e-liquids, and the user behaviors that can influence the yield of nicotine and other toxicants (Shihadeh and Eissenberg 2015). This close focus includes providing details of devices (e.g., voltage of the power supply, heating element resistance) and components of e-liquids (e.g., propylene glycol, vegetable glycerin, other additives), and measuring user puff topography. Standardization of procedures for producing and delivering the aerosol is likely a necessary component of at least some in vivo and in vitro work. Preclinical work examining the effects of e-cigarette aerosols is a clear research need and, again, the standardization of procedures for production and delivery of the aerosol is necessary. To enhance relevance, the parameters of aerosol production should span the range of those seen with humans (Shihadeh and Eissenberg 2011).

The huge variety of products of different origin and design, the rapid emergence of new products, and the varied ways in which consumers use these products make the development of standard measurement conditions challenging (Famele et al. 2015). Accordingly, research is needed to understand how different design features relate to potential toxicity—for example, if the compounds in e-cigarettes are affected by heating, changes in chemical composition, or pH; if these compounds are absorbed into the bloodstream; and how additives to the e-liquid affect the bioavailability of these compounds, among other considerations. Research is also needed to understand whether potential health risks may be ameliorated by changes in product engineering.

Conclusion

- 1) Nicotine exposure during adolescence can cause addiction and can harm the developing adolescent brain.

- 2) Nicotine can cross the placenta and has known effects on fetal and postnatal development. Therefore, nicotine delivered by e-cigarettes during pregnancy can result in multiple adverse consequences, including sudden infant death syndrome, and could result in altered corpus callosum, deficits in auditory processing, and obesity.
- 3) E-cigarettes can expose users to several chemicals, including nicotine, carbonyl compounds, and volatile organic compounds, known to have adverse health effects. The health effects and potentially harmful doses of heated and aerosolized constituents of e-cigarette liquids, including solvents, flavorants, and toxicants, are not completely understood.
- 4) E-cigarette aerosol is not harmless “water vapor,” although it generally contains fewer toxicants than combustible tobacco products.
- 5) Ingestion of e-cigarette liquids containing nicotine can cause acute toxicity and possibly death if the contents of refill cartridges or bottles containing nicotine are consumed.

SECTION 4. ACTIVITIES OF THE E-CIGARETTE COMPANIES

Introduction

This chapter focuses on the companies that are active in the production, distribution, or marketing of e-cigarettes in the United States and examines the potential influence of these companies on the use of e-cigarettes, particularly among youth and young adults. The e-cigarette marketplace is complicated by the fact that some brands and devices are owned by tobacco companies, while others are independently owned. This chapter will refer to the e-cigarette companies as a whole but, when necessary, will distinguish between the e-cigarette brands that are owned by tobacco companies and others that are independently owned. The chapter covers manufacturing and price, marketing and promotional activities, the retail environments for e-cigarette products, exposure to marketing and receptivity to such activity, and the effects of e-cigarette marketing activities on consumer behavior.

Manufacturing and Price

As discussed in Chapter 1, although the concept of e-cigarettes was initially introduced in the 1960s, the first-generation version of e-cigarettes was not developed and commercialized until the mid-2000s (Grana and Ling 2014). In the short period since the first appearance of e-cigarettes, the exponential growth in awareness and use of these products (Centers for Disease Control and Prevention [CDC] 2015), the rapid product development (Zhu et al. 2014), and the rapid evolution of both the e-cigarette market and the industry itself (Huang and Chaloupka in press) have been unprecedented. E-cigarettes were recently named a “disruptive innovation” that may change the existing tobacco market and displace conventional (combustible) cigarettes in a fore-seeable timeframe (Spielman and Azer 2013).

Consumer demand for a less harmful alternative to conventional cigarettes and the implementation of macro policies, such as those that restrict cigarette use or mandate clean indoor air, may influence the use of e-cigarettes (Pepper et al. 2014b; Rose et al. 2014). However, e-cigarette companies may play a critical role in shaping the market, affecting everything from the development and innovation of new products and brands to the manufacture, distribution, marketing, promotion, and pricing of the product— activities that parallel those in the cigarette industry.

This section describes and summarizes both the rapidly changing e-cigarette market and the activities of e-cigarette companies in the United States, providing a broad overview of the

major players. These participants include the major tobacco companies and other manufacturers. The chapter also addresses how the companies influence the e-cigarette market in the United States, focusing on the impact of product development and innovation, distribution channels, product availability, and pricing strategies, as well as the role of e-cigarette trade organizations and partnerships.

Overview of the E-Cigarette Market in the United States

For 2014, the value of the e-cigarette market in the United States was estimated at \$2.5 billion: 40% (\$1.0 billion) was for cigarette-like e-cigarettes (cigalikes), and 60% (\$1.5 billion) was for tank-style e-cigarettes, mods, and other types of “vaporizers” (Wells Fargo Securities 2015a) (Table 4.1). The market was projected to grow to \$3.5 billion, a rise of 40%, in 2015 (Rose et al. 2014) (Table 4.2). Total sales of e-cigarettes in convenience, food, drug, and big-box stores (such as Walmart), which are tracked by commercial market research companies (such as Nielsen), were estimated to be \$900 million in 2014. There was an additional estimated \$500 million in online sales, and \$1.1 billion in sales in “vape shops” and other channels, which are not currently tracked by commercial market research companies (Table 4.1) (Wells Fargo Securities 2015b).

Distribution and Purchase Channels

E-cigarettes entered the U.S. market around 2006–2007, and since that time the distribution and purchase channels for these products have evolved greatly. Initially they were sold exclusively by Internet retailers, but then selling activity expanded to shopping mall kiosks and conventional retail outlets and, more recently, to “vape shops” and some pharmacies (Rose et al. 2014; Lee and Kim 2015).

Some companies operating in the U.S. market have their own manufacturing facilities in this country, but companies generally import parts or even complete products from abroad, almost exclusively from China (Barboza 2014). Manufacturers and importers distribute their products via a wide number of channels, such as the companies’ own e-commerce websites and/or retail outlets. In 2010, the most popular channels for selling e-cigarettes and their accessories directly to consumers were websites and third parties, such as retail outlets (Linarch Information Solutions 2012). Many e-cigarette manufacturers and importers, including the big-brand companies and those supplying products to “vape shops,” rely on distributors and retailers to deliver the products to the consumer (Linarch Information Solutions 2012).

The emergence of e-cigarette devices and products resulted from the endeavors of a few entrepreneurs and widespread Internet and television advertising (Grana et al. 2013; Rose et al. 2014). It is noteworthy that the product class took hold when e-commerce was rapidly expanding in the United States, and major social media platforms—such as Facebook (founded in 2004), YouTube (2005), and Twitter (2006)—were emerging. In such an environment, information about a new product like e-cigarettes could be rapidly disseminated across geographic boundaries, and new products and technologies could be speedily adopted. This process is partly reflected by the Google search volume of queries related to e-cigarettes; the volume of queries surpassed those for nicotine replacement therapy products and snus by 2008 (Ayers et al. 2011).

Table 4.1. Estimated e-cigarette market size in 2014 (\$ billion)

	Convenience, food, drug, and big-box stores	Online	Other channels (“vape shops” and other untracked retail channels)	Total
E-cigarettes	0.6	0.2	0.2	1.0
Vapors/tanks/mods	0.3	0.3	0.9	1.5
Total	0.9	0.5	1.1	2.5

Source: Wells Fargo Securities (2015a).

Table 4.2. Estimated e-cigarette market size in 2015 (\$ billion)

	Convenience, food, drug, and big-box stores	Online	Other channels (“vape shops” and other untracked retail channels)	Total
E-cigarettes	0.7	0.4	0.4	1.5
Vapors/tanks/mods	0.4	0.4	1.2	2.0
Total	1.1	0.8	1.6	3.5

Source: Wells Fargo Securities (2015a).

Manufacturers noticed the fast rise in consumer interest in e-cigarettes, so they quickly pushed to expand the sale of their products to brick-and-mortar retail stores. Sales of cigalikes and related products were first observed in Nielsen’s store-scanner database in 2007, and between 2009 and 2012, retail sales of e-cigarettes expanded to all major markets in the United States (Huang and Chaloupka in press). This growth coincided with a surge in marketing expenditures by the e-cigarette companies across all media platforms (Kim et al. 2014; Kornfield et al. 2015). The products sold in these conventional channels were predominantly disposable and rechargeable cigalikes (Giovenco et al. 2015; Huang and Chaloupka in press), but retail stores started to carry tank-style e-cigarette devices as well (CSP Daily News 2014; Giovenco et al. 2015).

Today, e-cigarette brands, such as MarkTen (manufactured by Altria) and VUSE (manufactured by Reynolds American Inc.), are available in more than 70,000 retail stores across the country, and their availability is expanding rapidly (Wells Fargo Securities 2014b). E-cigarettes were more likely to be available in retail locations in neighborhoods with a higher median household income and a lower percentage of African American and Hispanic residents; these sales patterns are consistent with patterns of use of these products observed among youth, young adults, and adults more generally (see Chapter 2). Notably, the price of conventional cigarettes and the existence of comprehensive smokefree laws were inversely associated with the availability of e-cigarettes (Rose et al. 2014).

Through growth in their sales, tank-style e-cigarettes (also known as mods) and advanced personal vaporizers (APVs) have begun to play an increasingly important role in the e-cigarette market (Wells Fargo Securities 2015a). “Vape shops,” which provide a range of e-cigarette devices and products, have emerged as the primary retail channel for consumers seeking such products (Lee and Kim 2015). Unlike conventional retail outlets, “vape shops” sell a wide range of more complex and powerful tank-style e-cigarettes and many different types of liquids for e-cigarette devices (e-liquids or e-juices) (Sussman et al. 2016).

The rise of “vape shops” can be attributed to a number of factors. First, in the past, most of these establishments offered a wide range of e-cigarettes and e-liquids, allowed users to sample different types of flavored e-liquids at no cost, and permitted the trial use of various types of e-cigarettes. Most of these establishments sell products made by independent

companies, as opposed to products manufactured by the major conventional tobacco companies (Kamerow 2014; Sussman et al. 2016). As a result, “vape shops” can serve as an information hub where consumers can easily obtain knowledge about (and gain experience with) a wide range of e-cigarettes and related products (Sussman et al. 2016). However, the information provided may be misleading or misinterpreted (Cheney et al. 2016). Second, unlike traditional retail outlets, “vape shops” are usually equipped to provide consumers with individualized information about how e-cigarette products can be used to best satisfy the user’s preferences; this capability may be important as e-cigarette products become more diversified and sophisticated. Because of the diversity of these products, some of these establishments provided free samples of different flavored e-liquids and allowed trial use of different e-cigarettes before actual purchase in an attempt to compete with traditional retail outlets. Under the deeming rule published in May 2016, free samples of e-liquids containing nicotine were banned (*Federal Register* 2016). Third, “vape shops” serve as a place for e-cigarette users to socialize.

Some “vape shops” also host various events, including competitions (also known as cloud chasing), that build loyal customer bases by creating a sense of community and camaraderie among customers (Sussman et al. 2014; Cheney et al. 2015; Lee and Kim 2015). Additionally, a 2015 study of “vape shop” owners found that customers view the owners as important sources of health information, which could include information related to cessation (Cheney et al. 2016). However, the owners reported (a) obtaining their information from YouTube or industry sources but finding the research hard to understand and (b) looking for government sources but not finding them. Estimates of the number of “vape shops” in the United States have varied greatly due to the lack of a clear definition of what constitutes such an establishment. The low end of these estimates puts the number around 3,500 (Klein 2013; Lee and Kim 2015), while intermediate estimates indicate that there are about 6,000–15,000 “vape shops” in this country (Bour 2015; Wells Fargo Securities 2015b). One high estimate is that in 2014 there were as many as 35,000 such shops in the United States (Kamerow 2014).

Product Evolution

E-cigarette products have evolved and diversified rapidly since they entered the U.S. market (see Chapter 1). Detailed information about different types of e-cigarette products has been presented elsewhere (Grana et al. 2014). Over time, with consolidation of e-cigarette companies and technological improvements, the manufacturing process has become more standardized, enabling the production of e-cigarette products with a more effective and more consistent dose and delivery of nicotine and flavorings, and a more consistent generation of aerosol (Goniewicz et al. 2013a,b; Farsalinos and Polosa 2014; Saitta et al. 2014).

Many e-cigarette manufacturers make multiple types of e-cigarette products. For example, the NJOY brand has not only disposable and rechargeable cigalikes but also tank-style e-cigarette devices, which are larger than cigalikes and include options for refills and batteries. In addition, NJOY sells a variety of flavored e-liquids, although in California, flavors appealing to minors (e.g., strawberry and cookies and cream) are prohibited (*State of California v. Sottera, Inc.* 2010). Within each product type, there are many different brands, albeit the brands are often very similar. For example, NJOY, blu, Logic, Mystic, and many other brands of rechargeable e-cigarettes differ very little from each other with regard to the flavors and types of products offered (e.g., cigalike, tank style) (Zhu et al. 2014). A study examining the growth of brands and flavors between 2012 and 2014 found that older brands

were more likely to involve cigalikes, while newer brands were more likely to offer tank-style devices and mods (Zhu et al. 2014). As tank systems and mods become more popular, the distinction between a closed system and an open system becomes more important. In a closed system, components cannot be customized. In this case, the e-liquid is “locked in”; the amounts of e-liquid, level of nicotine, and flavors are dictated by the manufacturer. Because users cannot mix their own e-liquids or refill the cartridges or tanks, there is less risk of spillage, nicotine overdose, and accidental ingestion. In addition, users cannot change the power source, adjust the voltage, or customize the atomizers. Many brands offer only closed-system devices (e.g., Vype, Vapestick, and FIN). Most cigalikes are closed systems, sold primarily online or in conventional retail outlets, and are favored by the larger e-cigarette companies, likely because of the high profit margins from the e-liquid refill cartridges and the nature of the distribution paths.

Open systems, in contrast, allow for personalization and customization: Users can mix their own e-liquid, choosing different e-liquid bases, flavors, and nicotine concentration levels. Users can also adjust the voltage, customize the atomizers, and/or modify the aesthetics and shapes/sizes of their devices (Popken 2014; Richtel 2014c; Lee and Kim 2015). Tanks and mods/APVs are open systems sold primarily in “vape shops” or online. While research has demonstrated that more-experienced e-cigarette users prefer open system mods (Farsalinos et al. 2014), one analyst has suggested that closed systems may better facilitate consistent and enforceable product and manufacturing standards (Wells Fargo Securities 2014a).

Beyond the increased variety over time of products, their components, and related products (including accessories such as carriers, lanyards, stickers, and sleeves), the products continue to appeal to consumers through the incorporation of increasingly complex technologies—including location tracking; Bluetooth connectivity; social networking functions and integration with users’ social media accounts; and entertainment functions, such as playing music and videos (Bauld et al. 2014; Brown and Cheng 2014; Honig 2014).

The terminology for e-cigarettes has also expanded. Terms such as e-cigars, e-hookahs, vaping pens, hookah pens, and personal vaporizers are used interchangeably (or preferentially) by some users (Richtel 2014b). In addition, the spectrum of use has broadened, as some e-cigarettes that involve open systems are also used for the aerosolization of marijuana and cannabis oil (Bryan 2014; Morean et al. 2015) and could be adapted for other illicit substances (see Chapter 2).

Worldwide, more than 95% of e-cigarettes sold are thought to have been manufactured in China (Jourdan 2014), most in one city—Shenzhen (Barboza 2014). A few large manufacturers (e.g., Joyetech, Kimree, and First Union) dominate the market (see Appendix 4.1 for descriptions of the major e-cigarette manufacturers).⁵ Most of these manufacturers provide supplies to many different e-cigarette companies, including American companies marketing conventional cigarettes, as well as independent e-cigarette companies. Some companies (e.g., Gamucci) have an exclusive manufacturer in Shenzhen.

Some e-cigarette companies have begun to locate their manufacturing base in the United States. Reynolds American, for example, has a factory in Tobaccoville, North Carolina, to manufacture its VUSE brand and strongly emphasizes this location as part of its marketing

⁵ All appendixes and appendix tables that are cross-referenced in this chapter are available only online at <http://www.surgeongeneral.gov/library/reports/>.

strategy (CSP Daily News 2015). White Cloud, another U.S.-based company, moved its cartridge-filling production from China to Tarpon Springs, Florida, in May 2014 (McConnell 2014), and the U.S.-based brand Mistic has announced plans to move its manufacturing from China to Greenville, North Carolina (Bettis 2014).

Evolution of Market Share in the E-Cigarette Market

Although the e-cigarette market in the United States has changed significantly since its emergence, these changes have not been studied extensively. This section documents market share by brand for e-cigarette sales in retail outlets tracked by Nielsen, using data from the forthcoming study by Huang and Chaloupka (in press) and supplemented with data from industry reports issued by a number of investment banks. These data, available in Appendix 4.5, clearly show the dynamic changes in the e-cigarette market, and these changes are important to understand in terms of access to and marketing of these products to youth and young adults.

E-Cigarette Sales in Tracked Retail Outlets

Total sales of e-cigarettes in tracked retail channels have surged exponentially since 2010, increasing from only a few million dollars per quarter in 2010 to more than \$170 million in the last quarter of 2014 (Figure 4.1). Although Reynolds American's VUSE brand did not enter the market until late 2013, its sales climbed rapidly in 2014 because of heavy promotion and price discounts. At the end of 2014, VUSE had become the market leader with the highest quarterly sales at \$56 million. Blu (owned by Lorillard and thus now by Imperial Tobacco) was the market leader for most of 2013 and 2014, with an average \$60 million in quarterly sales. During this time the number of its distribution points rose from 60,000 to more than 150,000 because of its acquisition by Lorillard and subsequent marketing and promotion efforts.

After doubling every year between 2010 and 2013 (Figure 4.2) in the tracked retail channels, rates of increase in the sales of e-cigarettes decelerated significantly, with total sales actually declining in the second quarter of 2014. The deceleration may reflect, in part, the shift away from cigalikes to tank-style devices, mods, and other e-cigarette products among users; the sales of these devices are not tracked as well, which makes it difficult to know the true trends in sales (see Tables 4.1 and 4.2).

Figure 4.2 presents sales data by product type. Sales of disposable e-cigarettes trended upward from 2010 to 2013, increasing from a minimal amount in 2010 to almost \$100 million in the second quarter of 2013, but 2014 showed a substantial decline, with the value only about \$50 million for the final quarter of that year. The figure shows a clear pattern of seasonality in sales for disposables: sales usually rose in the first quarter of the year—potentially reflecting the effect of New Year's resolutions among smokers who seek to use rechargeable e-cigarettes as a way to quit conventional cigarettes—but had subsequently declined during the rest of the year. Sales of e-liquid refills increased steadily over the 4-year period between 2010 and 2014 and reached \$80 million in the final quarter of 2014, representing approximately half of the total e-cigarette sales in the tracked retail channels.

In 2014, more than 85% of e-cigarette sales occurred in the tracked retail and online channels, including certain convenience stores and food, drug, and big-box stores (Wells Fargo Securities 2015a; see Table 4.1). It was estimated that 20% of *all* e-cigarette sales (including e-cigarettes and tanks/mods) in 2014 occurred online, while 44% of *all* e-cigarette

sales occurred in “vape shops” and other untracked retail channels (Wells Fargo Securities 2015a; see Table 4.1).

Source: Huang and Chaloupka (in press).
Figure 4.2. E-cigarette sales in tracked channels by product type, 2010–2014.

Another important trend in e-cigarette sales is the growth of flavored products. Although some brands, such as NJOY, initially did not sell flavored e-cigarette products, most companies now offer some form of flavored varieties. Giovenco and colleagues (2015) found that sales of menthol-flavored e-cigarettes in traditional U.S. retail channels (e.g., convenience stores, grocery stores, pharmacies, and mass merchandisers) more than doubled between 2012 and 2013, increasing from \$96.4 million in 2012 to \$215.7 million in 2013. Sales of fruit-flavored e-cigarettes more than tripled during the same period, from \$4.9 million to \$16.7 million.

Sales of different types and brands of e-cigarettes likely differ by demographic group. For example, anecdotal evidence suggests that youth and young adults prefer pen-style devices, those that come in various shapes and styles, and devices that may be used interchangeably with e-hookahs (Richtel 2014b). Research also suggests that users may eventually graduate to more complex systems; more specifically, experienced users may be more likely to use tanks and mods (Farsalinos et al. 2014). Unfortunately, sales data by demographics are very limited, and studies have not yet examined how sales of e-cigarette products differ by demographic classification.

Production of E-Liquids

E-liquids used in closed-system devices usually are produced in the United States and then shipped to China to be included in the assembly process. For example, MarkTen, blu, and NJOY manufacture their own e-liquids in the United States, which then are sent to China before the final product is assembled there.

In the United States, one of the biggest players in the premixed e-liquid market for refillable e-cigarettes is Johnson Creek Vapor Company (2011), which claims to be the world's leading manufacturer of e-liquid and the first company to produce and manufacture e-liquid in the United States. Johnson Creek has not disclosed the suppliers of its nicotine solution.

Impact of E-Cigarette Price on Sales and Use of These Products

This section summarizes the limited evidence on the impact of e-cigarette prices on the sales and consumption of these products. The sizable body of research examining the effects of taxes and prices on the sale and use of conventional cigarettes (Chaloupka and Tauras 2011; International Agency for Research on Cancer 2011) leads to the conclusion that price increases resulting from higher excise taxes are effective tools for reducing cigarette consumption, especially among youth.

Trends in E-Cigarette Prices over Time

A study by Huang and Chaloupka (in press) documented and analyzed the relationship between real price and sales volume for both disposable and rechargeable e-cigarettes by using Nielsen data, which reflected the e-cigarette (predominantly cigalikes) sales and prices in retail stores tracked by Nielsen.

Figure 4.3 presents U.S. data on real price (determined by adjusting the prices to the value of the U.S. dollar in the fourth quarter of 2014) and sales volume for disposable e-cigarettes between 2010 and 2014 based on data from Huang and Chaloupka (in press). The average price for a single disposable e-cigarette declined from approximately \$17 in the first

quarter of 2010 to less than \$9 in 2014. In terms of volume, the estimate for disposables increased from far below 100,000 in the first quarter of 2010 to almost 11 million in the first quarter of 2014, before dropping to about 6.3 million in the final quarter of 2014. This graph reveals an association between real price and the sales volume for disposable e-cigarettes from 2010 to the second quarter of 2013: As real price declined over time, sales volume increased. Looking back, the rapid decline in the price of disposable e-cigarettes between 2007 and 2011 (Huang and Chaloupka in press) may have occurred because of improvements in product technology and industry promotion, which significantly cut the costs of producing such products (Bhatnagar et al. 2014; Wells Fargo Securities 2015c). The rather modest declines in prices since 2011 may reflect the fact that further technological improvements became less feasible (Wells Fargo Securities 2015c).

In terms of volume, the substantial decrease in 2014 may be partly attributable to consumers shifting away from cigalikes to tanks, mods, and other more powerful devices, for which sales were not tracked well.

Source: Huang and Chaloupka (in press).

Figure 4.3. Sales volume and price of disposable e-cigarettes, U.S. market, 2010–2014.

An inverse relationship is also evident between real price and sales volume for rechargeable e-cigarettes. Figure 4.4 demonstrates that when the real price went down, the sales volume increased, particularly after 2012. Between 2010 and 2014, the average unit price for rechargeables decreased markedly, dropping from \$37 in the first quarter of 2010 to \$12 at the end of 2014. However, there were more price fluctuations than were found for disposable e-cigarettes (Figure 4.3). The price fluctuations for rechargeables were likely because of the change in product mix and the influx of various new types and brands of these devices during this period (Bhatnagar et al. 2014; Wells Fargo Securities 2015c). Sales volume increased dramatically between 2010 and 2014, rising from a minimal amount at the beginning of 2010 to about 3 million units in the last quarter of 2014.

Impact of E-Cigarette Prices on E-Cigarette Sales

In one of the first studies to explore the effects of e-cigarette prices on the sales of these products, Huang and colleagues (2014b) estimated, from Nielsen data, both the own-price elasticity and the cross-price elasticity of demand for e-cigarettes (disposable or rechargeable)

and studied the impact of conventional cigarette prices and smokefree policies on e-cigarette sales. Own-price elasticity is a measure showing how much demand for a product will change given a change in its price, while cross-price elasticity is a measure showing how much demand for a product will change given a change in another product's price. Using data from Nielsen's commercial retail store scanning service, this study employed fixed-effects models to estimate elasticity of demand and associations between e-cigarette sales and either the prices of conventional cigarettes or smokefree policies from 2009 to 2012. Results demonstrated (a) that e-cigarette sales were quite responsive to own-price changes (estimated own-price elasticities for disposable e-cigarettes centered around -1.2 [a 10% increase in price would decrease sales by 12%], while those for rechargeable e-cigarettes were approximately -1.9 [a 10% increase in price would decrease sales by 19%]) and (b) that disposable e-cigarettes appeared to be emerging as substitutes for rechargeables (a 10% increase in rechargeable e-cigarette prices increased sales of disposable e-cigarettes by about 5%). This study concluded that policies increasing the retail prices of e-cigarettes—such as imposing taxes or limiting rebates, coupons, and discounts—could potentially lead to significant reductions in e-cigarette sales and that variations in tax policy by product type could lead to substitution between product categories. It is important to note that “vape shops” were not included in these data, as Nielsen collects data only from convenience, food, drug, and big-box stores.

Although these results provide evidence that changing the price of e-cigarettes affects the number sold, the potential effects of the price of conventional cigarettes on the purchase of e-cigarettes are less clear. Huang and colleagues (2014b) found no consistent or statistically significant relationship between the price of conventional cigarettes and the sale of e-cigarettes. In contrast, Grace and colleagues (2015), who measured the cross-price elasticity of e-cigarettes and conventional cigarettes using simulated demand for the latter in a sample of New Zealand smokers, found that the cross-price elasticity of e-cigarettes was significantly positive, suggesting that e-cigarettes may be partially substitutable for conventional cigarettes. Thus, the use of e-cigarettes may increase as the price of conventional cigarettes increases.

Source: Huang and Chaloupka (in press).

Figure 4.4. Sales volume and price of rechargeable e-cigarettes, U.S. market, 2010–2014.

Other evidence suggests that the potential impact of price changes on the use of e-cigarettes may differ by demographic characteristics. Relationships between the smoking of conventional cigarettes and socioeconomic status (SES) are well documented in the literature, and additional evidence has demonstrated that youth and young adults, and those with low SES, tend to exhibit higher sensitivity to changes in the price of conventional cigarettes (International Agency for Research on Cancer 2011; U.S. Department of Health and Human Services [USDHHS] 2012). Therefore, youth and young adults, as well as low-SES persons, may be more price-sensitive in the purchase of e-cigarette products, and thus they may be more likely to stop using e-cigarettes as their price increases. These potential connections between the price of e-cigarettes and their use should be examined carefully as more data become available.

Marketing and Promotion of E-Cigarettes

Marketing is an important tool for industries to use in influencing consumer preferences, and the potential for marketing to influence smoking behaviors has been a source of public health concern for many years (DiFranza et al. 1991; USDHHS 2000, 2012; National Cancer Institute [NCI] 2008). Research has demonstrated a causal relationship between tobacco marketing and smoking, with the majority of research focusing on the impact of tobacco marketing on the initiation of smoking by youth (Biener and Siegel 2000; USDHHS 2012). For adolescents, studies have found cross-sectional and longitudinal associations between the intensity of cigarette marketing and initiation of smoking, brand awareness, brand preferences, attitudes toward smoking, susceptibility to smoking, and smoking behaviors (O’Connell et al. 1981; Chapman and Fitzgerald 1982; McNeill et al. 1985; Charlton 1986; Potts et al. 1986; Aitken et al. 1987; Goldstein et al. 1987; Aitken and Eadie 1990; Botvin et al. 1991; DiFranza et al. 1991; Klitzner et al. 1991; Pierce et al. 1991; Botvin et al. 1993; Hastings et al. 1994; Pierce et al. 1994; Coeytaux et al. 1995; Evans et al. 1995; Pierce and Gilpin 1995; Richards et al. 1995; Slade et al. 1995; Unger et al. 1995; Pollay et al. 1996; Schooler et al. 1996; Gilpin and Pierce 1997; Lam et al. 1998; Feighery et al. 2006). A review of these and other studies led the 2012 Surgeon General’s report to conclude that exposure to advertising causes the initiation of smoking (USDHHS 2012).

In general, product marketing is designed to inform people about the products being offered (and thus develop brand “awareness”) and to persuade people to buy particular brands (i.e., develop brand “preference”). Branding is particularly important for products considered to be “commodities,” such as conventional cigarettes and e-cigarettes, where the offerings are similar and branding differentiates the products (Rossiter and Bellman 2005; NCI 2008). Marketing is particularly critical for e-cigarettes, as new products must be introduced to potential users (Sethuraman et al. 2011).

Like marketers of conventional cigarettes, marketers of e-cigarettes use a number of channels and tactics to advertise and promote their products. These channels have included extensive marketing on the Internet and advertising in mainstream media, including popular magazines, retailer point-of-sale ads, product placement on popular media, and even television commercials—an advertising option unavailable to cigarette manufacturers because of regulatory policies (Legacy for Health 2014; Ganz et al. 2015). E-cigarette brands

also use web-sites to interact directly with their customers through direct-to-consumer marketing (e.g., direct mail and direct e-mail) and social media channels, such as Facebook, Twitter, and Instagram (Huang et al. 2014a; Richardson et al. 2014; Ganz et al. 2015).

Marketing Expenditures

E-cigarette manufacturers currently are not required to report marketing expenditures to any regulatory agency (Boxer et al. 2013; *Federal Register* 2015). Using proprietary data from Kantar Media, however, Kornfield and colleagues (2015) tracked marketing expenditures (television, print, radio, and Internet) back to 2008 for approximately 130 e-cigarette brands (note that many e-cigarette products are not branded, and thus these data are not complete). Kornfield and colleagues (2015) found minimal spending through 2010, followed by an acceleration in spending from \$12 million in 2011 to \$125 million in 2014 (Figure 4.5). Not shown in the figure is that in 2012, more than 60% of advertising expenditures were for blu (then owned by Lorillard, now Imperial Tobacco), which was the market leader (Kornfield et al. 2015). The trajectory for spending was consistent with the pattern for product sales, particularly for the most dominant brands (Figures 4.1 and 4.5).

Annual marketing expenditures for conventional cigarettes (\$9.2 billion in 2012) dwarf the \$125 million in 2014 for e-cigarettes (Federal Trade Commission 2015a,b; Kornfield et al. 2015). However, the available data about e-cigarette marketing also underestimate total marketing expenditures. Not included are expenditures for retail marketing, social media, and sponsored events, all of which are essential components of the industry's integrated marketing strategy. In the absence of regulation, television advertising for e-cigarettes will continue, as the two largest tobacco companies moved promotions of MarkTen (Altria) and VUSE (Reynolds American) from test markets to national distribution in 2014 (Kornfield et al. 2015; Truth Initiative 2015; Cantrell et al. 2016).

Tobacco marketing and surveillance systems—including the Trinkets & Trash archive maintained by the Rutgers University School of Public Health and the Stanford Research into the Impact of Tobacco Advertising (SRITA) research group—collect examples of e-cigarette advertising and promotions and make these available to users through image-rich websites (see Trinkets & Trash [<http://www.trinketsandtrash.org>] and Stanford Research into the Impact of Tobacco Advertising [http://tobacco.stanford.edu/tobacco_main/index.php]).

Magazine and Print Advertising

Print has been the dominant channel for tracked expenditures of traditional e-cigarette advertising, representing 84% of annual expenditures in 2014 (Kornfield et al. 2015; Figure 4.5). A study by Richardson and colleagues (2014) collected U.S. advertisements for all noncombustible tobacco products (i.e., e-cigarettes, snus, dissolvables, and chew/dip/snuff) for a 3-month period in 2012 through Mintel, which tracks direct mail and opt-in e-mail ads, and Competitrack, which monitors 21 other media sources. Metadata for identified ads showed advertising for e-cigarettes in print, television, radio, online, direct mail, and e-mail. The three most common media were print, television, and e-mail, and spending was highest for print ads (Richardson et al. 2014). An analysis of industry marketing data by the American Legacy Foundation (now called Truth Initiative) reported that 47% of U.S. teens (12–17 years of age) and 82% of young adults (18–21 years of age) were exposed to magazine advertising for e-cigarettes in 2014; popular venues included tabloids, entertainment weeklies, and men's life-style magazines (Truth Initiative 2015).

Research indicates that e-cigarette advertising in magazines with high teen readership is on the rise (U.S. Congress 2014). From 2012 to 2013, the number of e-cigarette advertisements in magazines with high youth readership was four times the number in magazines with high adult readership (U.S. Congress 2014). Recent studies using data from Kantar Media and GfK MRI (the latter measures media audiences and consumer insights; see <http://www.mri.gfk.com>) on e-cigarette advertisements show that blu led all e-cigarette brands in magazine advertising and that respondents had the highest recall of blu advertisements (Legacy for Health 2014).

A content analysis by Banerjee and colleagues (2015) of print magazine tobacco ads for 2012–2013, using data collected from Kantar Media, identified 171 e-cigarette ads over this period, 27 of which were unique. Ads were found in 24 magazines, 11 of which had been identified in prior studies as having youth and young adult readerships greater than 2 million per year or for which the teen portion of the audience was more than 10%. By number, ads for e-cigarettes were second only to those for conventional cigarettes and higher than the numbers for moist snuff, cigars, and snus. Eighty-five percent of the content in e-cigarette ads focused more on a theme of logos (i.e., logic or facts to support a position) than on a theme of emotional appeal.

Source: Data for 2010–2013 (Q2) from Kornfield and colleagues (2015, p. 110) and adapted with permission from BMJ Publishing Group Limited. Data for 2013 (Q3)–2014 from Kantar Media (unpublished data).

Figure 4.5. Quarterly promotional spending for e-cigarettes, 2010–2014.

In examining persuasive themes, the study found that ads used several approaches, including highlighting the conventional advantages of the product—such as a focus on customer satisfaction—and emphasizing the quality of the product or price (85.2%) (Banerjee et al. 2015). The ads also used the comparative approach, such as portraying the product as being different from other products, being smokefree, or being exempt from use in areas where conventional cigarettes are prohibited. Figure 4.6 shows examples of the claims in e-cigarette marketing. In terms of images, 100% of the ads included the brand name and an

image of the product. In addition, ads were most frequently full-page advertisements (89.9%), usually placed the product in a way that drew attention to it (92.6%), and most often used six or more colors (85.2%), which the authors noted increases the attention-grabbing ability of the ads (Banerjee et al. 2015).

A different content analysis of magazine ads for e-cigarettes, this one for a 3-month period in 2012 (Richardson et al. 2014), found health-related themes and non-health-related attributes—such as romantic, sexual, or sociability content, with the highlighting of taste as the most frequent selling proposition (see Figure 4.6, parts B–D for examples). All ads in this analysis were found to contain links to a product’s website. When examined by readership, e-cigarette ads were found to have run in magazines with mostly White-male readers and, to a lesser extent, magazines targeting White women. The analysis noted that ads were targeted to a magazine’s readership, with different ads shown in the White, male-oriented *Rolling Stone* publication as compared with the female-dominated *Us Weekly*.

Television Advertising to Youth and Young Adults

The increasing frequency and reach of advertising on television raises concerns about the potential impact of promoting nicotine products and renormalizing smoking through that medium, particularly for youth (Hodge Jr 2013; Duke et al. 2014; Grana and Ling 2014). At least 40 unique advertisements for e-cigarettes appeared on U.S. television in 2013 and early 2014 (Farrelly et al. 2015). For example, e-cigarette ads were featured in the Super Bowl broadcast, which reached an estimated audience of more than 100 million persons in 2012 (Deans 2012). The Truth Initiative (formerly the American Legacy Foundation) found that in 2014, television advertising reached similar proportions of youth (62% of 12- to 17-year-olds) and young adults (64% of 18- to 24-year-olds) (Truth Initiative 2015). Using proprietary data from Nielsen, Duke and colleagues (2014) estimated that 50% of U.S. youth were exposed to e-cigarette ads on television in 2013 and that 80% of this advertising was for blu (Lorillard, now Reynolds American). On average, those exposed saw 21 ads between October 2012 and September 2013. Between 2011 and 2013, exposure to e-cigarette advertising on television increased dramatically, by 321% for young adults (18–24 years of age) and 256% for adolescents (12–17 years of age) (Duke et al. 2014).

The same study (Duke et al. 2014) found that more than 75% of the exposure of youth to e-cigarette ads occurred on cable networks. The study found television ads for several different brands—including blu, FIN, Starfire, and NJOY—during a 9-month period in 2013. The most widely aired ad was for blu, featuring a celebrity and closing with the tagline “we’re all adults here. It’s time to take back your freedom” (Duke et al. 2014, p. 6).

Sponsorships

After the Master Settlement Agreement in 1998, sponsorship of events with a significant youth audience, such as concerts and athletic events, was banned for conventional cigarettes. However, e-cigarettes do not fall under these parameters, and recalling the early marketing of conventional cigarettes, e-cigarette brands have used sponsorships to increase the awareness and appeal of their label and product. For example, in 2011 blu sponsored a NASCAR driver and had its own car in some races (PRNewswire 2011). Additionally, blu has handed out free samples during large events and has even sponsored events at music festivals (PRNewswire 2013; blu eCigs 2014). Further, conservative estimates indicate that in 2012 and 2013, free samples were provided by six companies at 348 events, most of these events having high

participation by youth (Durbin et al. 2014). Under the deeming rule published in May 2016 (currently under litigation), free samples were banned (*Federal Register* 2016).

Digital Landscape for E-Cigarettes

The Internet has been widely used to promote cigarettes, cigars, and smokeless products (Ribisl 2003; Freeman and Chapman 2007; USDHHS 2012). This medium—through websites, message forums, and social media—has been heavily used to sell and glamorize e-cigarettes and their use. Nearly all teens 13–17 years of age (92%) use the Internet daily, and 73% of teens access the Internet via smartphones (Lenhart 2015). In 2015, a study conducted by the Truth Initiative indicated that 40% of youth (13–17 years of age) and 57% of young adults (18–21 years of age) had seen e-cigarette advertising online (Truth Initiative 2015).

Figure 4.6. (Continued).

Price promotions are not just involved in sales at brick-and-mortar stores; they are also offered by online stores and through social media. Grana and Ling (2014) found that 80% of websites indicated a sale price or discount, while Huang and colleagues (2014a) found that 34% of commercial tweets mentioned the words “price” or “discount.” Both Facebook and Twitter provide opportunities for brands and companies to offer online coupons and discounts (Discount Coupons for blu n.d.; Vapor4Life n.d.). In a study of online e-cigarette retailers, 28% of the web-sites offered a promotion, such as a discount, other free items, or a loyalty program (Williams et al. in press). Without age restrictions or age verification, youth can access these websites easily and thus obtain the discount or coupon (Williams et al. in press).

H. Cleaner than cigarettes

**ADULT SMOKERS:
IF YOUR CAR COULD TALK...**

It would insist you try blu™ electronic cigarettes. Smoke-free, ash-free, and odor-free means blu eCigs® electronic cigarettes give you complete freedom. Imagine smoking satisfaction without rolling down the car windows! No more offensive, lingering odors in your car's upholstery. No more fuss over messy ashes that missed the ashtray. Since your car can't talk, it won't ask you to try blu eCigs e-cigarettes. So we will... take back your freedom: have a blu e-cigarette.

Visit www.blucigs.com for more information.

TRADITIONAL SMOKING COMES AT A COST

The cost of smoking traditional cigarettes goes well beyond what you pay at the cash register. With traditional cigarettes, you are limited in the places you can smoke, you make many compromises, and your smoking often affects those around you. FIN e-cigarettes have no smoke and no odor, leaving you free to smoke in far more places, and with far less negative impact.

ESCALATING COST OF CIGARETTES

With the rising cigarette tax and increased restrictions, smoking traditional tobacco cigarettes has become more profitable. FIN electronic cigarettes are not only easier to use, but it can cut the cost of smoking almost in half. Come experience freedom from expense and restrictions.

COST OF SOCIAL ACCEPTANCE

There are significant restrictions and an smoking in public spaces for many reasons. Because electronic cigarettes, create no smoke and no odor, FIN grants you far greater freedom to smoke publicly, and is socially accepted.

FIN PRODUCT LIFE

Each disposable FIN e-cigarette is the equivalent of 2 packs or 40 traditional cigarettes. With FIN rechargeable products, you get even more life and satisfaction out of a single e-cigarette. Using FIN saves time and money while resupplying you conveniently.

THERE ARE MANY WAYS TO SAVE WITH FIN

FIN gives smokers a smoking alternative, the often unmet convenient and cost effective electronic cigarette options, from disposables to rechargeables to complete kits.

Figure 4.6. E-cigarette marketing claims.

However, under the deeming rule, websites cannot sell e-cigarettes to youth under the age of 18, so access will likely be curtailed as a result (*Federal Register* 2016). The following sections review three basic categories of online e-cigarette content: websites that sell e-cigarettes, manufacturer-sponsored brand name websites, and e-cigarette promotions on social media websites (including Facebook, Twitter, and YouTube).

Websites Selling E-Cigarettes

Tobacco industry analysts estimate that online sales accounted for approximately 30% of e-cigarette sales volume in the first quarter of 2015 (Wells Fargo Securities 2015a). Some Internet vendors sell their own brands exclusively (e.g., Mystic, Green Smoke), while a large

number are online stores that sell many brands and varieties of products (Zhu et al. 2014; Williams et al. in press).

Although the marketers of e-cigarettes have made claims that differ from those made for conventional cigarettes (such as use for smoking cessation, which is illegal without being an approved cessation drug or device), a content analysis of e-cigarette marketing (Grana and Ling 2014) and the observations of tobacco marketing surveillance systems point to several similarities, including the use of young, attractive models; lifestyle claims; and celebrities. Other claims made in e-cigarette advertising have been used in the past by conventional cigarette brands (such as having fewer carcinogens, lower risk of tobacco-related disease) or by smokeless tobacco products (such as the ability to use them where smoking is prohibited) (Grana and Ling 2014). However, under the deeming rule that was published in May 2016, after August 8, 2016, e-cigarette manufacturers cannot make modified risk claims (*Federal Register* 2016) (although this provision has been challenged in pending lawsuits).

Formal analyses of marketing claims of branded e-cigarette sites that both promote and sell e-cigarettes provide details on the types of claims made in these channels. The study by Grana and Ling (2014) analyzed claims from 59 English-language websites over a 2-month period in 2011 and found four major thematic content areas: health- and cessation-related benefits, avoiding smokefree policies, lifestyle benefits, and product-engineering claims. Ninety-five percent of websites made explicit or implicit health-related claims, and 64% made claims related to cessation, often through the use of testimonials. Almost all (98%) included a comparison of the risks and benefits of e-cigarettes and conventional cigarettes; 95% included claims that e-cigarettes are cleaner; and 93% said they were cheaper. Claims regarding where e-cigarettes could be used were also common—with 88% claiming e-cigarettes can be used anywhere, and 71% pointing to e-cigarette use as a means of circumventing clean air policies. Figure 4.6 shows advertising that exemplifies these marketing claims for e-cigarettes.

Grana and Ling's (2014) analysis also points to the common use of lifestyle-related claims, a hallmark of traditional tobacco marketing: 73% of websites contained images or claims of being modern or glamorous. Websites also pointed to social advantages for users of their particular brand: 44% of claims pointed to increased social status and 32% to enhanced social activity, 31% suggested romantic advantages, and 22% used celebrities. Claims of increased social status, opportunity, and romance as well as the use of celebrities may resonate especially with youth and young adults (Grana et al. 2011).

A different content analysis, this one of the marketing messages of English-language branded e-cigarette retail sites, examined and compared websites for two different time periods (May–August 2012 and December 2013–January 2014) and found differences in claims between the two timeframes (Zhu et al. 2014). In comparing claims for brands available during both time periods with those that were newly available in 2013–2014, the authors found that products and advertising messages varied between the two samples. Brands analyzed from 2012 were significantly more likely than those in the later period to (a) claim that their products were healthier and less expensive than conventional cigarettes and could be used where smoking is prohibited and (b) indirectly claim their products were effective for smoking cessation through testimonials and other methods (Zhu et al. 2014). The study also found an increase from one period to the next in the number of branded retail websites and the number of flavors per brand advertised on a website, as well as the likelihood of a web-site offering e-cigarette hardware and such other products as e-liquids and

e-hookahs or other products that did not resemble cigalikes (Zhu et al. 2014). The study's findings suggested that the emphasis for newer brands had shifted from comparing them with conventional cigarettes to a focus on their role as new nicotine delivery systems.

Williams and colleagues (in press) used a standardized search strategy employed in their earlier study of websites selling cigarettes (Ribisl 2003) to identify 995 English-language websites selling e-cigarettes in 2014. The authors performed a content analysis on the 281 most popular websites, as judged by data on traffic. Most of the websites were based in the United States (71.9%), the United Kingdom (16.7%), and China (5.3%), and they offered a variety of products, but more sold e-cigarette starter kits (92.5%) than disposables (55.2%). Most offered flavors, with the most popular being fruit (79.4%), candy (75.2%), coffee (68.0%), and alcohol (45.6%). Although 71.5% featured some type of health warning, 69.4% claimed health advantages over other tobacco products, and 32.7% claimed that the product helped people to quit smoking conventional cigarettes. The sites also featured endorsements or mentions of celebrities using the products (Stanford Research into the Impact of Tobacco Advertising n.d.a.). Physicians and other health professionals provided endorsements as well.

Elsewhere, Cobb and colleagues (2015) conducted a forensic analysis of websites that sold e-cigarettes and participated in affiliate advertising on the Internet. In addition to identifying multiple layers of redirection between online advertising by affiliates and websites selling e-cigarettes, the authors found that online advertisements and affiliate websites included cessation claims.

Research suggests Internet e-cigarette vendors have not routinely verified the age and identity of website visitors or blocked sales to minors. However, after August 8, 2016, due to the deeming rule, it has become illegal for online retailers to sell e-cigarettes to those under 18 (*Federal Register* 2016). In a survey of purchasing by youth, Williams and colleagues (2015) identified 98 web-sites selling e-cigarettes on which youth, 14–17 years of age, made purchase attempts using prepaid credit cards. In all, 18 (of 98) order attempts failed because of technical problems with the website or the payment system, all of which were unrelated to age verification. Of the remaining 80 orders, 75 (93.8%) were filled. Five vendors claimed to use a service offered by shipping companies to verify age at delivery, but none actually did. Although data are not available on the proportion of youth who purchase their e-cigarettes online versus buying them at retail outlets, this study suggests that youth would have ready access if they tried to purchase e-cigarettes online. The *Prevent All Cigarette Trafficking Act of 2009* requires Internet sellers of cigarettes and smokeless tobacco to, among other provisions, verify age of customers at the time of purchase and ensure that the deliverer checks identification at the time of delivery; stop Internet sales to minors; and pay applicable local, state, federal, and territorial taxes to reduce the price advantage of online sales. FDA regulation now prohibits the Internet sales of e-cigarettes to minors. However, there are currently no federal requirements for Internet vendors of e-cigarettes to check identification upon delivery or pay applicable taxes (Campaign for Tobacco Free Kids 2016).

The marketing of candy and fruit flavors may be one of the reasons that e-cigarettes appeal to youth (Grana and Ling 2014; Richtel 2014a; Zhu et al. 2014). Young adults (18–24 years of age) are more likely to use flavored tobacco products than are adults in the next age group (25–34 years of age) (Villanti et al. 2013). Zhu and colleagues (2014), who used three search engines (Google, Yahoo!, and Bing) and various keywords from May 2012 to January 2014 to identify a wide variety of e-cigarette brands and flavors, found 466 brands and 7,764 unique flavors, with 242 new flavors appearing each month. Other than tobacco flavor, the

most popular flavors were menthol (92.1%), fruit (84.2%), dessert/candy (79.9%), and alcohol/ drinks (77.5%). Additionally, in their content analysis of e-cigarette retail websites, Grana and Ling (2014) found that such flavors as coffee, fruit, and candy were offered on most sites. Further, flavors were being sold under brand names similar to cereal and candy products that appeal to youth, such as Wrigley's Big Red Gum (Daniels 2015).

Tobacco Industry Corporate and Brand Websites

Three categories of e-cigarette brands have emerged within the U.S. market: brands developed by cigarette manufacturers (i.e., MarkTen, VUSE), brands acquired by cigarette manufacturers (i.e., blu, Green Smoke) (Table 4.3), and brands that have no affiliation with a cigarette manufacturer (e.g., NJOY, FIN). A content analysis of websites for these three types of brands suggested that those *developed* by cigarette manufacturers may be marketed more cautiously than brands *acquired* by cigarette manufacturers or brands that have no affiliation with a cigarette manufacturer (Seidenberg et al. 2016). Table 4.4 compares and contrasts some key features of the web-sites by manufacturer affiliation. It shows, for example, that access to websites of brands developed by cigarette manufacturers (or a subsidiary) was restricted to users 21 years of age and older (MarkTen), and user registration was required (i.e., the user needed to input personal information such as name, address, and birthdate) for VUSE. In contrast, websites for brands with no affiliation with a cigarette manufacturer and those acquired by cigarette manufacturers were accessible to users 18 years of age and older via self-reporting of age, with the exception of 21st Century Smoke. In addition, VUSE e-cigarettes were not sold online (they were sold only in retail outlets), and they were available in a single nicotine level with limited flavor options (except for forthcoming tank versions), while MarkTen could be purchased online. The websites for both MarkTen and VUSE mentioned selling flavored e-cigarettes. As far as e-cigarette brands not having an affiliation with a cigarette manufacturer or that were acquired by a cigarette manufacturer, all brands except Logic offered fruit, candy, or other flavors. Further, all of the unaffiliated brand websites sold e-cigarettes online and offered multiple nicotine levels. Most websites offered nicotine-free options and flavored e-cigarettes as well (Seidenberg et al. 2016). The Green Smoke website even provided a link to guide customers in finding the proper nicotine level for their cartridges (Green Smoke E-Vapor n.d.).

Social Media Promoting E-Cigarettes

E-cigarettes have been widely promoted on social media platforms such as YouTube, Twitter, Instagram, and Facebook; most of these social media sites do not require age verification. YouTube is the most popular video-sharing website globally and features many e-cigarette videos. Luo and colleagues (2014) used various search terms to identify 196 unique videos in February 2013 that were portraying e-cigarettes and found that 94% of the videos were "pro" e-cigarettes, 4% were neutral, and 2% were "anti" e-cigarettes. Those authors found that the three most common genres were advertising of products, user sharing, and product reviews. Of the "pro" e-cigarette videos, 84.3% featured links to websites selling e-cigarettes, and 71.4% claimed that e-cigarettes were a healthier alternative to conventional cigarettes. Finally, the "pro" videos received more visits and were rated more favorably than were the small number of "anti" videos.

Table 4.3. Mergers, acquisitions, partnerships, and other agreements in the e-cigarette industry

Date	Purchaser	Acquisition target	Partnerships and other agreements	Deal size ^a	Geography ^b
December 2011	Japan Tobacco	—	Ploom (partnership)	Not disclosed	United States

Source: Various news sources and companies' websites, SEC (Securities and Exchange Commission) reports, and press releases as of January 25, 2016.

^aDeal size refers to prices at the time of the announcement, not necessarily the final transaction price.

^bGeography refers to the country in which the acquisition target was registered.

The authors of another study, this one a content analysis of 365 e-cigarette videos on YouTube that ran at some time from June 2007 to June 2011, estimated that more than 1.2 million youth and a total of 15.5 million people worldwide were exposed to these videos (Paek et al. 2014). In addition to looking at viewership, the content analysis examined the type, sponsorship, and health claims of the videos. Just 16% of the videos were formal advertisements or news clips, and 79.2% of the content was coded as appearing to have been generated by users. Videos emphasized economic, psychological, and social benefits, and health claims included e-cigarettes being less harmful than conventional cigarettes, healthy, and providing help in quitting smoking. Most (85.2%) videos in the sample were sponsored by e-cigarette companies or their associates, with an additional 10% coming from individuals who did not mention a specific website or company. Interestingly, videos sponsored by marketers contained a significantly lower level of health claims than did those from laypeople

(users) and, not surprisingly, contained a higher level of information cues (e.g., product contents, price, distribution channel).

Table 4.4. Comparison of website access restrictions, online sales, nicotine levels, and flavors among e-cigarette brands with no cigarette manufacturer affiliation, brands acquired by cigarette manufacturers, and brands developed by cigarette manufacturers

		E-cigarette brands (10)	
	Not affiliated with a cigarette manufacturer: NJOY, Logic, 21st Century Smoke, FIN, Nicotek, and Mystic (6)	Acquired by a cigarette manufacturer: blu and Green Smoke (2)	Developed by a cigarette manufacturer (or subsidiary): MarkTen and VUSE (2)
Website access	All websites (except 21st Century Smoke) have one-click access ^a or age verification to restrict initial access to people 18 years of age and older; 21st Century Smoke does not have any website restrictions for initial access.	Both sites have one-click access or age verification to restrict initial access to people 18 years of age and older (blu) and 21 years of age and older (Green Smoke).	MarkTen has age verification to restrict initial access to people 21 years of age and older. Before initial access, VUSE requires people 21 years of age and older to register first with the website.
Online sales	All brands can be purchased online.	Both brands can be purchased online.	MarkTen can be purchased online; VUSE cannot.
Multiple levels of nicotine	Among all brands, the level of nicotine varies by product. Some (e.g., blu, Logic Zero, 21st Century Smoke, Nicotek) offer products with 0% nicotine (by volume).	Among both brands, the level of nicotine varies by product.	For MarkTen, the level of nicotine varies by product. VUSE e-cigarettes contain 4.8% nicotine (by weight). VUSE tanks, set to come out in February 2016, will have different levels of nicotine (Kress 2015).
	Not affiliated with a cigarette manufacturer: NJOY, Logic, 21st Century Smoke, FIN, Nicotek, and Mystic (6)	Acquired by a cigarette manufacturer: blu and Green Smoke (2)	Developed by a cigarette manufacturer (or subsidiary): MarkTen and VUSE (2)
Flavors (other than tobacco and/or menthol)	All brands offer a variety of flavors, such as fruit and candy.	Both brands offer a variety of flavors.	MarkTen offers two flavors: fusion and wintermint. VUSE offers four flavors: crema, chai, berry, and mint (Kress 2015).

^aWith "one-click access," visitors to a website self-report on their age by identifying their age from a clickable pop-up box. For example, persons 18 years of age and older can browse the website, but those younger than 18 cannot.

A cross-sectional study of Twitter, a microblogging platform, that examined more than 74,000 tweets accessed through a licensed Twitter data provider over a 2-month period in 2012, found extensive marketing of e-cigarettes (Huang et al. 2014a). The majority of e-cigarette content during this period was advertising and promotion. In fact, 89.6% of the tweets contained commercial content (e.g., presence of branded promotional messages or hyperlinks to commercial websites), and only 11% identified as being non-sponsored or independent, reflecting individual opinions or experiences, or being linked to non-promotional content. Commercial tweets most commonly contained price promotions and

discounts (34.3%), with cessation-related claims included in 10.8% and lower percentages for health or safety (Huang et al. 2014a).

Jo and colleagues (2016), in a study of 2,847 tobacco-related tweets about price promotions and coupons, found that e-cigarettes, not conventional cigarettes, were the most frequently mentioned product (90.1%), and about one-third of all e-cigarette-related tweets included a discount code. The tweets also touted the relatively low price of e-cigarettes and made comparative claims about the health risks of the product.

Sponsored Online and Video Advertising

The study by Richardson and colleagues (2015) used information from the monitoring service Competitrack to analyze the volume and characteristics of industry-sponsored tobacco and e-cigarette online banner/ video advertisements in the United States and Canada in 2012–2013. This study found that online banner/video advertising—which embeds an ad or video on a web-site—was more commonly used for e-cigarettes than for conventional cigarettes. E-cigarette ads were often placed on music or entertainment (39.1%) sites, which the authors noted attract a sizeable number of youth and young adults. The most frequent theme for the 24 online banner or video e-cigarette ads (promoting five e-cigarette brands) analyzed was that the product was more “green” or environmentally friendly than conventional cigarettes (54.2%), followed by less harmful than cigarettes (37.5%), and being an alternative to conventional cigarettes when someone could not smoke (33.3%).

E-Cigarettes in the Retail Environment

Conventional Tobacco Retailers (Convenience Stores, Pharmacies, Tobacco Shops)

As of December 2015, 48 of the 50 states prohibited sales of e-cigarettes to minors (National Conference of State Legislatures 2015), but compliance of retailers with youth-access laws has not yet been studied. FDA is actively enforcing the federal minimum age requirements. As of August 8, 2016, the federal deeming rule bans the sale of e-cigarettes to minors under the age of 18 and requires photo identification for those under age 27 (*Federal Register* 2016). In the past few years, brick-and-mortar retailers have surpassed the Internet as the dominant distribution channel for e-cigarettes. For example, after Lorillard acquired blu in 2012, the number of retailers selling this brand increased from 13,000 to 127,000 in just 1 year (Esterl 2012; Bannon 2013). In California, the proportion of licensed tobacco retailers that sold e-cigarettes increased from 12% in 2011 to 67% in 2014 (Chapman 2015).

E-cigarettes are widely available in convenience stores, a type of establishment that 4.1 million U.S. teenagers visit at least once per week (Rose et al. 2014; Sanders-Jackson et al. 2015a). According to a 2013 state-sponsored survey that included a sample of approximately 7,300 licensed tobacco retailers in California, e-cigarettes were sold in more than half of convenience stores, pharmacies, and liquor stores and in nearly all tobacco shops (California Department of Public Health and California Tobacco Control Program 2014).

Only three studies have examined the retail availability of e-cigarettes near schools. In a 2012 nationally representative sample of tobacco retailers, the presence of a public school within 1,000 feet was not related to the availability of e-cigarettes (Rose et al. 2014). In a study that examined a much larger buffer zone in Kentucky, 88% of schools in two counties were located within 1 mile of a retailer that sold e-cigarettes (Hahn et al. 2015). As for

colleges, disposable and/or rechargeable e-cigarettes were available at 60% of tobacco retailers near campuses in North Carolina and Virginia in 2013, a more than two-fold increase from the previous year (Wagoner et al. 2014). A pilot study examining tobacco point-of-sale advertising and promotion in the central Harlem neighborhood of New York City found that 26% of stores had e-cigarette advertising on the building's exterior (Ganz et al. 2015). External ads included those located less than 3 feet above the ground at the eye level of children—a placement that was outlawed for conventional cigarettes by the Master Settlement Agreement—and featured flavored products (Ganz et al. 2015).

Unlike conventional cigarettes, e-cigarettes appear to be relatively less prevalent at stores in economically disadvantaged communities. In an analysis that examined data from two studies that had used representative samples of U.S. tobacco retailers, e-cigarettes were less likely to be sold than conventional cigarettes at stores located in economically disadvantaged neighborhoods and in neighborhoods with a higher proportion of African American residents (Rose et al. 2014). These patterns are consistent with evidence that e-cigarette marketing in other channels targets higher income non-Hispanic White males (Emery et al. 2014). However, the retail availability of e-cigarettes has changed at different rates in different neighborhoods. In a study of U.S. food stores, only 3% of stores located in non-Hispanic White and Hispanic neighborhoods sold e-cigarettes in 2010; none of the stores in predominantly African American neighborhoods sold them (Khan et al. 2014). Three years later, the figures were 36% in pre-dominantly non-Hispanic White neighborhoods, 18% in Hispanic-majority neighborhoods, and 19% in African American-majority neighborhoods. Notably, these data were collected before the two largest U.S. tobacco companies launched MarkTen (Altria) and VUSE (Reynolds American) in late 2013. Thus, the industry's current influence on disparities in the retail availability and marketing of e-cigarettes cannot be readily estimated from the studies reviewed.

Two studies examined retail data about e-cigarettes as a function of state and/or county smokefree air laws (Huang et al. 2014b; Rose et al. 2014). In one of the studies, which used data collected in two studies that used independent samples of U.S. tobacco retailers, the odds of selling e-cigarettes were greater for retailers in states with weaker smokefree air policies, even after controlling for store type, price of conventional cigarettes, and neighborhood demographics (Rose et al. 2014). A similar inverse relationship was found between sales of disposable e-cigarettes (as measured by retail scanner data in 52 U.S. markets from 2009 to 2012) and the proportion of the population protected by 100% smokefree policies covering all indoor areas of bars, restaurants, and work-places (Huang et al. 2014b). Taken together, these results suggest that e-cigarettes are, at least initially, more likely to be sold in communities with weaker smokefree policies. Few retail surveillance studies have characterized promotion, placement, or price for e-cigarettes (Hsu et al. 2013; Wagoner et al. 2014; Ganz et al. 2015). In a study of licensed tobacco retailers in Florida, advertising for e-cigarettes was more prevalent on the exterior than the interior (50% vs. 11%) (Kim et al. 2015). In the study by Wagoner and colleagues (2014), the presence of e-cigarette advertising near college campuses in North Carolina and Virginia tripled on store exteriors and quadrupled in store interiors in just 1 year. Although the price of rechargeable units decreased significantly, there was little evidence of price discounting for any e-cigarettes (Wagoner et al. 2014). The low visibility of price discounts at the point of sale suggests that marketing for e-cigarettes favors a "pull" strategy, relying on direct mail and e-mail coupons and special offers to entice customers to retail locations.

“Vape Shops”

“Vape shops” specialize in the sale of refillable devices and tank systems, typically offer a tasting menu of flavors, and sometimes feature a lounge area where customers can “vape” while socializing (Lee and Kim 2015; Sussman et al. 2016). “Vape shops” have been excluded from most studies about the retail marketing of e-cigarettes, in part because the environment is so different from that of conventional tobacco retailers (Lee and Kim 2015) and because so few states require these establishments to obtain a tobacco retailer license, effectively keeping them out of the sampling frame for many studies and making the monitoring and enforcement of laws difficult (Lee et al. 2014).

Anecdotal evidence suggests that “vape shops” currently do not have readily visible branded signs and displays that characterize the retail marketing of other tobacco products. Even though the relationship between the “vape shop” industry and the tobacco industry can be adversarial (Sussman et al. 2016), one study found that the marketing practices of these establishments closely resemble the current and former strategies that tobacco companies have used to market other tobacco products (Cheney et al. 2015). According to this study, “vape shop” owners and managers in Oklahoma used free samples, loyalty programs, sponsored events, direct mail, advertising through social media, and price promotions targeted at particular consumers, such as college students (Cheney et al. 2015). No other study about marketing by “vape shops” has been published. Numerous gaps exist in research about “vape shops,” including information on consumer behavior, the use of tracking systems for sales data, marketing surveillance, purchases by youth, and the opinions of retailers and the general public about regulations. Spatial analyses are needed to determine whether “vape shops” are clustered near schools or college campuses, whether other neighborhood demographics are correlated with the location of these establishments, and how such associations, if present, have changed over time and in response to state and local policy interventions. The proportion of “vape shops” where workers mix solutions of liquid nicotine on site is not known, and the absence of uniform safety pre-cautions regarding handling and spills poses additional concern for regulation (ChangeLab Solutions 2014). Under the deeming rule that was published in May 2016, “vape shops” that mix and sell e-liquids are both retailers and manufacturers and, therefore, are subject to the provisions in the deeming rule and the Tobacco Control Act that apply to both (*Federal Register* 2016).

Exposure and Receptivity to Advertising for E-Cigarettes

Exposure

Given industry data about increasing expenditures for e-cigarette advertising and extending its reach, the high levels of advertising awareness reported in studies of youth and/or young adults are not surprising. An online panel of U.S. youth (13–17 years of age) and young adults (18–21 years of age) conducted in February 2014 found that awareness of e-cigarette advertising was greatest for retail advertising, followed by awareness of advertising on television and online (Truth Initiative 2015). In this study, and compared with the entire population, awareness among current smokers of e-cigarette advertising was higher across all channels and higher for online ads than for television ads (Legacy for Health 2014).

In school-based surveys of middle and high school students in Connecticut, gas stations and television were the dominant channels in which students reported recently seeing e-

cigarettes advertised or sold (Krishnan-Sarin et al. 2015). A different pattern was observed in a convenience sample of college students in Hawaii, where the figures for seeing ads were 59%, online; 58%, television; 71%, malls; 41%, gas stations; and 47%, convenience stores (Pokhrel et al. 2015). Elsewhere, in an online experiment, 56% of adolescents (13–17 years of age) who had never used e-cigarettes reported seeing at least one televised advertisement previously, and there were modest, but statistically insignificant differences in exposure by smoking status and race/ethnicity ($p < .10$) (Farrelly et al. 2015).

The National Youth Tobacco Survey reported that in 2014, 18.3 million middle and high school students were exposed to e-cigarette advertising from at least one source (CDC 2016b). In this nationally representative sample of U.S. middle and high school students, nearly 7 out of 10 reported seeing an e-cigarette advertisement in that year. The most common places for exposure among middle school students were retail stores (52.8%), the Internet (35.8%), television and movies (34.1%), and newspapers and magazines (25.0%). Similarly, high school students reported the highest exposure at retail stores (56.3%) and then the Internet (42.9%), television and movies (38.4%), and newspapers and magazines (34.6%). Among both middle school and high school students, exposure through retail stores was higher among non-Hispanic Whites than non-Hispanic Blacks. However, non-Hispanic Blacks had higher exposure to e-cigarette advertisements on television and in movies than non-Hispanic Whites. Females had higher exposure than males to advertisements on the Internet and in newspapers and magazines.

Receptivity to Advertising

Receptivity to tobacco marketing is a well-established risk factor for tobacco use by adolescents and young adults (NCI 2008; USDHHS 2012), and two studies adapted measures of receptivity to the marketing of tobacco in research on e-cigarettes. In one study, college students from a southwestern state who watched three advertisements for different brands of e-cigarettes in an online survey used a 7-point scale to rate how enjoyable, likable, and appealing the ads were; results suggested moderate receptivity (mean of 51 on a scale ranging from 7 to 126) and significant differences between brands (Trumbo and Kim 2015). In the other study, Pokhrel and colleagues (2015), using a sample of college students from Hawaii, adapted a multi-item scale of liking advertisements from studies about alcohol (Unger et al. 2003) and two items from the most commonly used measure of receptivity to tobacco marketing (Pierce et al. 1998). This study observed low levels of liking advertisements (all below the scale mid-point) (Pokhrel et al. 2015). The extent to which youth and young adults who are receptive to e-cigarette marketing are also receptive to tobacco marketing has not been studied. However, the extent to which advertising strategies for e-cigarettes mimic strategies used by tobacco companies suggests that the two measures of receptivity could be highly correlated.

Effect of E-Cigarette Advertising on Behavior

Associations with E-Cigarette Use and Intentions to Use

Evidence that advertising for conventional cigarettes increases product initiation among never users, discourages quit attempts in current users, and encourages relapse in those trying to quit is well established (NCI 2008; USDHHS 2012). However, while fewer studies have

focused on e-cigarette advertising in particular, the available evidence suggests that e-cigarette advertising has similar effects, although additional research is recommended. A search for studies of youth or adults that either (a) manipulated exposure to e-cigarette advertising or measured self-reported recall of advertisements, (b) assessed the frequency of exposure to advertising in one or more channels, or (c) measured receptivity to e-cigarette advertising yielded 10 studies that addressed the impact of advertising on the use of or intentions to use e-cigarettes. One experiment tested whether seeing television advertising for e-cigarettes predisposed adolescents to try these products (Farrelly et al. 2015). Among adolescents (13–17 years of age) who had never used e-cigarettes, a single exposure to a set of four televised advertisements for popular brands resulted in significantly greater intention to try e-cigarettes—more than 50% higher in the treatment group than the control group (Farrelly et al. 2015). Another study examined responses to e-cigarette advertisements among young adults (Trumbo and Kim 2015); among a convenience sample of college students who watched three television ads for e-cigarettes, greater receptivity to e-cigarette advertising was associated with significantly higher odds of intending to use e-cigarettes in the future, but the analysis did not adjust for prior use or individual demographics (Trumbo and Kim 2015).

Very few cross-sectional or longitudinal surveys have examined associations between adolescents' exposure to e-cigarette advertising and either trial or regular use of such products. An analysis of the 2011 National Youth Tobacco Survey found that adolescents who reported frequent exposure to protobacco advertising at the point of sale and on the Internet (e.g., seeing ads most of the time or always) had significantly higher odds of ever using e-cigarettes, and there was a dose-response association between the number of marketing channels to which they were exposed and ever use (Agaku and Ayo-Yusuf 2014).

Surveillance research that differentiates exposure to advertising for e-cigarettes from exposure to ads for conventional tobacco products would be useful to establish whether exposure to e-cigarette advertising is correlated with product use and contributes to product initiation and product use among young people who were not tobacco users to start. It bears mentioning here that a generation of U.S. youth has grown up without any television or billboard ads for conventional cigarettes. In this context, research is needed to understand at what age young people understand that e-cigarette advertising depicts the use of e-cigarettes rather than the smoking of conventional cigarettes and to examine whether there are spillover effects of marketing for e-cigarettes on the use of conventional tobacco products.

In the study from Hawaii (Pokhrel et al. 2015), researchers examined the association between exposure to e-cigarette advertising and product use using a convenience sample of approximately 300 college students in that state. The study found that more frequent exposure to e-cigarette advertising—as measured by exposure in any of multiple channels (e.g., newspapers, magazines, Internet, television billboards, sporting/cultural events, convenience stores, gas stations, grocery stores, and malls)—was associated with significantly higher odds of ever using e-cigarettes, and receptivity to e-cigarette advertising was associated with higher odds of past-month use, even after adjustments for smoking status and individual demographics.

Two studies strongly support the association between exposure to e-cigarette advertising and youth susceptibility to and use of e-cigarettes (CDC 2016a; Mantey et al. 2016). Both studies examined data from the 2014 National Youth Tobacco Survey, a survey of more than 20,000 U.S. middle and high school students. The studies assessed self-reported levels of exposure to e-cigarette ads on the Internet, in newspapers and magazines, at retail stores, and

on television or in movies, and used multivariate logistic regression models to examine the relationships between marketing exposure and e-cigarette susceptibility and use. Exposure to each type of e-cigarette marketing was significantly associated with increased likelihood of ever having used and current use of e-cigarettes among middle and high school students (CDC 2016a; Mantey et al. 2016). Exposure was also associated with susceptibility to use e-cigarettes among current nonusers. In multivariate models, as the number of channels of e-cigarette marketing exposure increased, the likelihood of use and susceptibility also increased (Mantey et al. 2016).

One concern is that e-cigarette advertising may perpetuate dual use of conventional cigarettes and e-cigarettes, a concern that comes from the visual depictions of e-cigarette use that may serve as smoking cues to current and former smokers of conventional cigarettes, increasing the urge to smoke and decreasing intentions and efficacy to quit or abstain from smoking (Glynn 2014; Grana and Ling 2014; Maloney and Cappella 2016). Consistent with cue-reactivity studies about conventional cigarettes, exposure to e-cigarette use in a laboratory was associated with increased urge to smoke conventional cigarettes among smokers and an urge to use e-cigarettes among users of that product (King et al. 2015). Whether exposure to depictions in advertising of the use of e-cigarettes triggers urges to begin or continue to smoke conventional cigarettes or weakens users' resolve to quit has received little attention. This is particularly important because rates of cigarette smoking among youth in the United States are at an historic low (CDC 2014).

Associations with Knowledge, Risk Perceptions, and Other Attitudes

Advertising is an important source of information about e-cigarettes for youth and adults (de Andrade et al. 2013; Pepper et al. 2014a), and there is emerging evidence about how unregulated advertising for e-cigarettes may influence consumer perceptions about product safety. One study of adolescents (Farrelly et al. 2015) and three studies of adults (Pokhrel et al. 2015; Sanders-Jackson et al. 2015b; Tan et al. 2015a) examined the associations between exposure to e-cigarette advertising and knowledge or perceptions of these products.

Among U.S. adolescents (13–17 years of age) who had never used e-cigarettes, a single exposure to a set of four televised advertisements was associated with significantly higher odds of agreeing that the products can be used without affecting those around you and with lower odds of agreeing that the products are harmful (Farrelly et al. 2015). Compared with the control group, the treatment group reported significantly more positive attitudes about the benefits of using e-cigarettes. Elsewhere, in an online survey representative of U.S. households, 57% of young adults (18–34 years of age) were aware that some e-cigarettes contain nicotine, but more frequent exposure to e-cigarette advertising at point of sale, in mass media, and in social media (the three variables combined) was associated with a significantly higher likelihood of answering this question incorrectly (Sanders-Jackson et al. 2015b).

In the previously cited study of college students in Hawaii (Pokhrel et al. 2015), greater receptivity to e-cigarette marketing—but not more frequent exposure to the advertising of these products—was associated with significantly greater endorsement of beliefs about harm reduction for e-cigarettes (e.g., safer, improves health, helps to quit). A different study referred to an online survey of U.S. adults (the Annenberg National Health Communication Survey [ANHCS]) in which surveyors measured the frequency of exposure to e-cigarette advertising (point of sale, mass media, and social media) and the degree to which participants

perceived those messages as negative or positive (Tan et al. 2015a). Compared with those who reported no exposure to advertising, those who held negative perceptions of these messages reported significantly greater perceptions of harm from breathing e-cigarette vapor. Taken together, the available evidence suggests that continued exposure to unregulated advertising likely promotes reduced perceptions of harm and toxicity and increased perceptions of the efficacy of e-cigarettes for quitting conventional cigarettes.

Whether the increasing amount of advertising and promotional activities for e-cigarettes serves to renormalize the smoking of conventional cigarettes—that is, to shift public norms back to acceptance of cigarette smoking—is also not known. In focus groups of adult smokers 45 years of age and older, participants expressed almost unanimous agreement, after seeing selected ads, that e-cigarette advertisements promote smoking as a socially desirable behavior (Cataldo et al. 2015). The analysis by Farrelly and colleagues (2015) also looked at outcomes for conventional cigarettes. After exposure to e-cigarette advertising, there were no significant differences between the treatment and control groups on intentions to smoke conventional cigarettes, attitudes toward those products, or perceived harm from cigarettes (even though there were differences between groups on their perceptions of e-cigarettes, as noted previously).

The study that used data from the ANHCS also tested the hypothesis that greater exposure to e-cigarette advertising was associated with weaker support for restricting cigarette smoking in public spaces (Tan et al. 2015b). Both more frequent exposure to e-cigarette advertising and the degree to which participants perceived those messages as positive correlated negatively with support for smoking restrictions. However, in models adjusted for demographic variables, neither measure predicted support for restricting smoking. Further research is needed to address whether the large amount of advertising for e-cigarettes weakens support for smokefree air laws and other tobacco control policies or supports other potential indicators of renormalizing smoking, particularly those indicators that are known risk factors for tobacco use by adolescents and young adults, such as descriptive norms (e.g., perceived prevalence), injunctive norms (e.g., peer acceptance or social acceptability), outcome expectations (e.g., perceived benefits), and attitudes toward the tobacco industry. Additional research is also needed to assess whether e-cigarette advertising that draws comparisons to conventional cigarettes could serve to undermine antismoking messages.

Evidence Summary

Although the e-cigarette marketplace is complicated by the differences in brands that are owned by tobacco companies versus independent brands, e-cigarette companies continue to change and to influence the manufacturing, price, marketing and promotion, and distribution of e-cigarette products and accessories. The e-cigarette market continues to grow, with projected sales of \$3.5 billion in 2015. Consolidation of e-cigarette companies has been rapid, with the first major merger taking place in 2012. These mergers and acquisitions are likely to continue, but the rate of consolidation may slow down as sales of cigalikes decelerate, and “vape shops” could have the potential to influence the e-cigarette marketplace based on the current structure of the marketplace and a regulatory landscape where federal regulation is

just beginning to be implemented. All of these factors create additional uncertainties and risks for both the existing independent e-cigarette companies and the large cigarette companies. This chapter has shown that many of the marketing techniques used by e-cigarette companies are similar to those used by the tobacco industry for conventional cigarettes, and that awareness by youth and young adults of this marketing, and their levels of exposure to it, is high. Further, tracking marketing expenditures and product sales is difficult because of the rapidly changing venues, including “vape shops,” use of social media, and online advertising.

Conclusion

- 1) The e-cigarette market has grown and changed rapidly, with notable increases in total sales of e-cigarette products, types of products, consolidation of companies, marketing expenses, and sales channels.
- 2) Prices of e-cigarette products are inversely related to sales volume: as prices have declined, sales have sharply increased.
- 3) E-cigarette products are marketed in a wide variety of channels that have broad reach among youth and young adults, including television, point-of-sale, magazines, promotional activities, radio, and the Internet.
- 4) Themes in e-cigarette marketing, including sexual content and customer satisfaction, are parallel to themes and techniques that have been found to be appealing to youth and young adults in conventional cigarette advertising and promotion.

SECTION 5. E-CIGARETTE POLICY AND PRACTICE IMPLICATIONS

Introduction

The previous chapters have set out what is currently known and not known about e-cigarettes. Despite the identified gaps in evidence and the dynamic, evolving patterns of the use of e-cigarettes, policy options are needed. These policy options are particularly important as they affect the use of e-cigarettes by youth and young adults. As this report has demonstrated, e-cigarettes are widely used by youth and young adults and are particularly risky for these age groups, and efforts to prevent their use by young people are needed. This chapter explores the policy landscape of e-cigarettes and sets forth recommendations that should protect the public's health, particularly as these policies relate to the short- and long-term health of youth and young adults.

The *Family Smoking Prevention and Tobacco Control Act of 2009* (or Tobacco Control Act) (2009) is meant to protect the health of the public, including young people. As previously discussed, on May 10, 2016, FDA published a final rule which deemed all other products, including e-cigarettes, meeting the definition of a tobacco product, except accessories of such products, to be subject to the *Federal Food, Drug, and Cosmetic Act*. This rule went into effect on August 8, 2016 (Federal Register 2016). Under the Tobacco Control Act, FDA likely will be required to consider the consequences of e-cigarette use for those who do not use tobacco products (as well as for those who do).

It can be stated that public health will be harmed *if* the availability of e-cigarettes:

- Increases exposure to nicotine among youth and young adults;
- Leads to the initiation of combustible tobacco smoking;
- Slows or prevents cessation of combustible products by nicotine-addicted smokers; or
- Increases the likelihood that former smokers will again become addicted to nicotine and/or use combustible products after being reintroduced to nicotine by e-cigarettes.

Potential harm also comes from secondhand exposure to the vapor or aerosol expelled from e-cigarette users. Secondhand exposure comes from inhaling the aerosol or contacting vapor-contaminated surfaces. Each of the potential negative consequences of the availability of e-cigarettes could lead to additional disease and premature mortality (Chapter 3).

Relative to efforts in cigarette and smokeless tobacco use prevention and control, a polarized debate has been in progress for several years over the role of e-cigarettes. There is general agreement that exclusive use of e-cigarettes poses a lower health risk to the individual than the extremely high health risks of using conventional, combustible tobacco products (Farsalinos and Polosa 2014; Grana et al. 2014a,b), although more research is needed on this as more becomes known about the harmful constituents of e-cigarettes (Sleiman et al. 2016). The controversy reflects the relative degree of emphasis given to the potential harm to adolescents and young adults from using e-cigarettes at one pole compared with the potential for reduced risk for established adult users of conventional cigarettes at the other (if they transition completely to e-cigarettes). Although this characterization does not reflect the complexity of the situation, it is useful in defining the potential tradeoffs that are implicit:

increased numbers of young people who are exposed to nicotine (and who may go on to conventional tobacco products) versus reduced health risks to individuals who completely switch from conventional, combustible tobacco products with their extremely high health risks. The discussion has become increasingly complicated as e-cigarette use has increased, and still-incomplete evidence potentially supports the views of those holding to both poles of the argument about reducing harm for the overall population. However, the majority of currently available scientific evidence does not support the recommendation to use e-cigarettes for the cessation of cigarette smoking (Hartmann-Boyce et al. 2016). Additionally, the use of e-cigarettes does not pose benefits to youth and young adults, and some data suggest that use of e-cigarettes could lead to the more harmful use of conventional cigarettes. In the context of young people, the precautionary principle should apply. The precautionary principle is defined by the United Nations Educational, Scientific and Cultural Organization (2005) as appropriate “when human activities may lead to morally unacceptable harm that is scientifically plausible but uncertain, actions shall be taken to avoid or diminish that harm” (p.14).

Critical Issues Related to Policies on E-Cigarettes in 2016

The E-Cigarette Landscape Is Dynamic and Evolving

Considerations of policy approaches to e-cigarettes offered in this report are made in the context of a rapidly changing marketplace for nicotine-containing products that now includes primarily conventional cigarettes, cigars, smokeless products, hookahs, and e-cigarettes (see Chapter 2). The manufacture and sales of nicotine-containing products, once dominated by a few large companies selling conventional cigarettes, have been transformed and now include many smaller companies that manufacture and sell through stores and “vape shops.” E-cigarettes are also sold through websites and in places where conventional cigarettes have long been available— convenience stores, pharmacies, gas stations, and grocery stores. Currently, hundreds of different e-cigarette products are on the market: designs are evolving rapidly, and major tobacco companies have their own lines of e-cigarette products. However, unlike the situation in the past in which the marketing of conventional tobacco products changed relatively slowly and there were limited media outlets, information about e-cigarettes is now promoted quickly through new media, as well as television, in part to reach key target groups, including youth and young adults.

As documented in Chapter 2, patterns of use are rapidly changing among adolescents and young adults, and likely among other groups within the population. For some of the most critical issues related to e-cigarettes, longitudinal data are not yet available because the use of these products is recent and constantly changing, and whether and when the patterns of use will stabilize is uncertain. Additionally, surveillance data and research on the wide-ranging consequences of e-cigarette use, including such key issues as the likelihood of addiction and other health problems for users and those passively exposed, are lagging behind the highly dynamic changes in the nicotine-product marketplace and the impact of these changes on the use of tobacco products, including e-cigarettes.

With regard to the potential health consequences of using e-cigarettes, estimates can be made based on knowledge of the characteristics and components of the aerosols that are then

inhaled. Unfortunately, evidence on short-term risks is limited, and long-term risks have not yet been identified because this would require monitoring users for years. For example, the impact of long-term inhalation of flavorings is not yet known. While some of the flavorings used in e-cigarettes are generally recognized as safe for ingestion as food, the health effects of their inhalation are generally unknown, and some flavorings have been shown to cause a serious lung disease, bronchiolitis obliterans, when inhaled (Kreiss et al. 2002; Barrington-Trimis et al. 2014). Whether the risk of lung disease or other disorders is truly substantial will require longer term epidemiologic and other research (Allen et al. 2016).

Thus, policy approaches must support control measures that (a) are as dynamic as the rapidly changing marketplace for e-cigarettes; (b) are supported by surveillance data; and (c) document in timely fashion the current status of the use of multiple types of tobacco products (including e-cigarettes); the emergence of state, local, tribal, and territorial policies; and the strategies being used to market these products.

Risk Tradeoffs Are Inherent for E-Cigarettes

Policy discussions about e-cigarettes have highlighted the potential tradeoffs in risk that could occur, particularly if e-cigarettes are positioned as a harm-reducing alternative to combustible tobacco products. Some have characterized these products as new technologies that might lead to a dramatic decline in the use of more dangerous forms of nicotine delivery, particularly conventional cigarettes and other combustible tobacco products (Abrams 2014; Cobb and Abrams 2014; Fagerström and Bridgman 2014; Grana et al. 2014a; Hajek et al. 2014; Henningfield 2014; Schraufnagel et al. 2014; West and Brown 2014; Lindblom 2015). Correspondingly, e-cigarettes have been proposed by some as a harm-reduction strategy and as a tool for smoking cessation, but the data to date do not support e-cigarettes for harm reduction or cessation (Siegel et al. 2011; Abrams 2014). By contrast, others are concerned that the availability of these new products will expand the number of youth and young adults who are exposed to nicotine and will eventually lead to exclusive use of other conventional tobacco products or dual use of both (e-cigarettes and conventional cigarettes) (Leventhal et al. 2015; Primack et al. 2015). Early longitudinal evidence provides some support for these concerns, although further research on this issue is still warranted.

As reviewed in Chapter 3, uncertainty remains about the health effects of e-cigarettes, particularly in the long term. Such effects will remain unknown until sufficient observations can be made over time. However, current knowledge of the characteristics of the inhaled aerosol from e-cigarettes suggests that if a current adult smoker of conventional cigarettes or other combustible tobacco products would use e-cigarettes exclusively instead of combustibles as a substitute nicotine delivery system, either en route to quitting tobacco completely or even as a long-term alternative, the risks of tobacco-related diseases would be reduced substantially compared with the risk imparted by continued smoking of conventional cigarettes (Fiore et al. 2014; USDHHS 2014; McNeill et al. 2015).

Still, as documented in Chapter 3, immediate and future health risks for youth and young adults who use e-cigarettes can be anticipated from exposure to nicotine, including addiction and harmful effects on brain development. Research must continue to characterize and quantify the full spectrum of potential health risks. Thus, in formulating policies related to the role of e-cigarettes in tobacco control and reducing the burden of tobacco-related disease, particularly among youth and young adults, e-cigarette products that deliver nicotine cannot

be considered a risk-free alternative to conventional cigarettes or other combustible tobacco products.

Any analysis of the potential increased risks and reduced harms of e-cigarette use also needs to consider data on the actual patterns of use because more of the risks affect youth and young adults and most of the potential benefits from reduced risk to health largely accrue to older cigarette smokers (Chapter 2). However, the reports of the tobacco industry to investors indicate the industry's interest in maintaining a broad pattern of use of nicotine-containing products, including conventional cigarettes, for decades to come (Calantzopoulos 2015). When considered in the context of the tobacco industry's past changes to product design (e.g., the creation of so-called "low-tar" cigarettes), the broader array of tobacco products now being discussed within the tobacco industry's plans (e.g., "Heat-Not-Burn" products) could slow cessation (because smokers have historically been drawn to reduced-harm products) and thus the overall decline of tobacco-related diseases (USDHHS 2014).

The dynamic balancing between risks and potential benefits of e-cigarette use will be swayed by the impact of such use on the use of other tobacco products by youth and young adults over time. The availability of e-cigarettes could adversely affect the use of tobacco products in this group by slowing the decline of smoking because this population will be exposed to nicotine and possibly become addicted to that substance. Indeed, data reviewed in Chapter 2 show evidence of such trends. Although the decline in rates of smoking conventional cigarettes and other combustible tobacco products is viewed universally as positive, the increasing number of youth and young adults who use e-cigarettes is a serious concern for all the reasons cited above. West and Brown (2014) and McNeill and colleagues (2015) suggest that the limited evidence from the United Kingdom does not support the concern that using e-cigarettes leads to the use of other tobacco products, and they maintain that the new adolescent users of these e-cigarette products include very few never smokers. However, the marketing of e-cigarettes is quite different between the United Kingdom and the United States, and the patterns of use, particularly among youth, are also quite different (European Parliament and Council 2014; England et al. 2015; Klein 2015; Leventhal et al. 2015; Primack et al. 2015; Barrington-Trimis et al. 2016; Wills et al. 2016; Institute for Global Tobacco Control n.d.). This pattern is also evident in some U.S. survey data from early in the era of e-cigarette use (as reviewed in Chapter 2), but not in more recent data, which indicate that e-cigarette products may contribute to nicotine addiction in a new generation of young people and thereby lead to increased use of a variety of nicotine delivery products, including combustible tobacco (Bauld et al. 2016; CDC 2016).

Fundamentally, the public health challenge and the charge to policy development can be framed as balancing the potential use of e-cigarettes as a new technology to reduce the use of combustible tobacco products against the possibility of expanding tobacco use among non-using youth and young adults, long-term former smokers, and other vulnerable populations (e.g., women of reproductive age and individuals with significant comorbidities, including those with mental health problems). Already, the e-cigarette companies are increasing the appeal of their offerings by enhancing the efficiency of nicotine delivery and using flavorings while they continue to advertise and promote their products aggressively.

Additional Evidence Suggested for Future Research

To characterize the critical balance for public health between the harms and potential benefits of e-cigarettes, more evidence on each of the elements that determine that balance

would be useful (Table 5.1). The needed data would come from surveillance of patterns of adoption of e-cigarettes and their use among the population generally, and particularly among the most critical populations for uptake: youth and young adults, former smokers, smokers, and other populations that are particularly at risk for adverse outcomes. Few studies have been done on the health risks posed by e-cigarettes and their potential effectiveness for smoking cessation (Hartmann-Boyce et al. 2016). However, as discussed in Chapter 2, there are still no standardized questions for research on e-cigarettes, and there is a need for further testing and development of e-cigarette questions and measurements.

Table 5.1. Comparative risk assessment: Potential harms and benefits of e-cigarettes

Harms	Benefits
Increased youth exposure to nicotine and potentially greater initiation of conventional cigarettes	Reduced disease risk for current smokers who completely switch to e-cigarettes
Slowing cessation by smokers due to nicotine addiction	Reduced disease morbidity for smokers with existing heart or lung disease who switch to e-cigarettes
Nicotine addiction in former smokers who begin to use e-cigarettes and possibly transition back to smoking	Potential for cessation of combustible products
Renormalization of nicotine use and smoking as acceptable	Fewer users of combustible products in the entire population
Future disease risks for youth who are exposed to nicotine	
Increasing the dual use of e-cigarettes with combustible products	
Serving as a “gateway” to the initiation of tobacco smoking	
Increased disease risk vs. complete cessation among those who use both e-cigarettes and combustible products	
Exposure to secondhand aerosol and lack of clean air	

To characterize the harms and benefits of e-cigarettes to public health, models are used to project their overall impact on public health (Levy et al. 2016). The use of modeling was described in detail in the 2014 Surgeon General’s report (USDHHS 2014). Conceptual models are needed to define the potential scenarios of changes in patterns of use among youth, young adults, adult smokers, former smokers, and other significant vulnerable populations. Figure 5.1 displays the range of patterns that are emerging with the wider adoption of e-cigarettes (Cobb et al. 2015; Vugrin et al. 2015). Researchers and public health officials can use dynamic population models (Mejia et al. 2010; Kalkhoran and Glantz 2015; Vugrin et al. 2015; Levy et al. 2016) to analyze the potential impact on population health of the relative probabilities of these various paths. Initial modeling has shown that the potential population health benefits are very sensitive to several factors: the levels of product risk, particularly those of e-cigarettes; patterns of initiation and switching; and the extent of dual use (Mejia et al. 2010; Cobb et al. 2015; Kalkhoran and Glantz 2015; Vugrin et al. 2015). The benefits of smoking cessation, particularly as early in life as possible, are well documented, but the epidemiologic evidence that reducing (but not quitting) cigarette consumption can lower the risk of all-cause mortality, or mortality from cardiovascular diseases, remains inconclusive (USDHHS 2014). Thus, more research is needed to better characterize the health consequences of dual use, in particular, in comparison to the recognized health benefits of complete smoking cessation (or potentially only e-cigarette use). Similarly, the health risks to former smokers who become exposed again to nicotine through e-cigarettes are uncertain.

Data are still limited on the risk of starting (or not starting) to smoke conventional cigarettes again (after successful cessation) following exposure to nicotine via e-cigarettes.

Source: USDHHS (2014). Adapted for this report.

Figure 5.1. Potential patterns of use of combustible products (CPs) and e-cigarettes (e-cigs).

As reviewed in Chapter 3, the long-term health risks of e-cigarettes will not be known for decades, although evidence to date suggests that they are generally less harmful than combustible products. However, less harmful is not the same as harmless. A substantial amount of evidence is available on some components of the aerosols inhaled by e-cigarette users. For many people, exposure to aerosol could occur across much of the life span, beginning in adolescence and even in childhood, when the lungs and brain are still developing. Flavorings are of particular concern with regard to pulmonary toxicity, as are the various effects of nicotine on the brain. Although the National Institutes of Health is now supporting a growing program of research on e-cigarettes, critical questions have not yet been answered. Given experiences with conventional cigarettes, long-term studies will be needed to identify the full health consequences of using e-cigarettes.

Thus, policies related to e-cigarettes will necessarily be made in the context of accumulating but incomplete evidence. The landscape is changing rapidly and, inevitably, research cannot keep pace. Quoting Sir Austin Bradford Hill's landmark paper on environment and disease: "All scientific work is incomplete—whether it be observational or experimental. All scientific work is liable to be upset or modified by advancing knowledge. That does not confer on us a freedom to ignore the knowledge we already have, or to postpone the action that it appears to demand at a given time" (Hill 1965, p. 300).

Potential Public Policy Approaches

In formulating public policies related to e-cigarettes, the context and possibilities vary across the national, state, local, tribal, and territorial governments and public entities. At the national level, progressive steps are being taken by FDA under the Tobacco Control Act. In 2010, the U.S. Court of Appeals for the D.C. Circuit determined that e-cigarettes and other products made or derived from tobacco may be regulated by FDA as tobacco products under the Tobacco Control Act and are not drugs or devices unless marketed for therapeutic purposes, such as being an aid to smoking cessation (*Sottera, Inc. v. Food and Drug Administration* 2010). In May 2016, FDA released its deeming rule to regulate the sale and distribution of e-cigarettes as a tobacco product (see Chapter 1) (*Federal Register* 2016). The rule is currently under litigation. The rule restricts the age of sale to those 18 years of age and older and requires retailers to check the age identification of young people under age 27, restricts vending machines to adult-only facilities, prohibits free samples, requires a health-warning statement about nicotine on packaging and in advertisements, requires domestic manufacturers to register their products and disclose the ingredients of their products, requires the reporting of the levels of harmful and potentially harmful constituents to FDA, allows FDA to review any new or changed products before being sold, and requires manufacturers to show scientific evidence that demonstrates the overall public health benefit of any product before it can be marketed as a modified risk tobacco product (*Federal Register* 2016). The Tobacco Control Act does not provide FDA with authority to impose taxes on tobacco products (Bhatnagar et al. 2014; Huang et al. 2014; Tobacco Control Legal Consortium 2015) or regulate indoor air quality (Schripp et al. 2013; Bam et al. 2014; Bhatnagar et al. 2014; Brandon et al. 2015a), occupational health and safety (USDHHS 2015; Whitsel et al. 2015), or hazardous waste disposal (Chang 2014; Krause and Townsend 2015).

FDA is not the only federal agency with potential jurisdiction over some aspect of e-cigarettes (Table 5.2). For example, the U.S. Department of Defense and U.S. Department of Veterans Affairs relate to specific populations, and other agencies relate to regulatory activities, such as the U.S. Federal Trade Commission, U.S. Department of Transportation, and the U.S. Environmental Protection Agency. Some agencies have coverage over specific areas, such as the General Services Administration and the National Park Service.

State, local, tribal, and territorial governments, as well as private entities, may also address these and other matters that are covered by the Tobacco Control Act (Freiberg 2012), and since 2010 many actions have been taken at the nonfederal level. State and local governments may utilize effective interventions that would also be expected to apply to e-cigarettes: increasing the price of tobacco products through taxation (Community Preventive Services Task Force 2012); creating and enforcing clean air policies (Hopkins et al. 2010); and passing comprehensive laws prohibiting sales to minors, combined with active enforcement (Community Preventive Services Task Force 2001). In addition, based on evidence that new e-cigarette products may addict a generation of young people to nicotine (Bunnell et al. 2015; CDC 2015b) and on mounting indications about potential harm from the use of these products in this population (Flouris et al. 2013; Barrington-Trimis et al. 2014; Goniewicz et al. 2014; Grana et al. 2014a; Pisinger and Dossing 2014; Goniewicz and Lee 2015), numerous health organizations have called for the extension of smoking-related policies to e-cigarettes (Association of State and Territorial Health Officials 2014; Bam et al.

2014; Bhatnagar et al. 2014; Offermann 2014; Schraufnagel et al. 2014; World Health Organization 2014a; Brandon et al. 2015a; USDHHS 2015). In the absence of causal findings that have guided evidence-based tobacco control for decades, the “precautionary principle” is relevant to decision makers as a guide to action to address e-cigarettes among youth and young adults. This principle supports intervention to avoid possible health risks when the potential risks remain uncertain and have been as yet partially undefined (Bialous and Sarma 2014; Saitta et al. 2014; Hagopian et al. 2015). However, the interventions should be appropriate to the currently perceived risk for future health consequences, in this case from e-cigarette use by youth, young adults, and pregnant women, as well as from the secondhand exposure of non-users to e-cigarette vapor.

Clean Indoor Air Policies

Clean indoor air or smokefree policies prohibit the use of conventional tobacco products in indoor public places, such as worksites, restaurants, bars, and casinos. Because most of these policies predate the rise of e-cigarettes, their language does not necessarily cover emissions from these products. To protect the public from both secondhand smoke and secondhand aerosol, smokefree air policies should be modernized to include e-cigarettes. Such policies will maintain current standards for clean indoor air, reduce the potential for renormalization of tobacco product use, and prevent involuntary exposure to nicotine and other aerosolized emissions from e-cigarettes (Ingebrethsen et al. 2012; Schripp et al. 2013; Goniewicz et al. 2014; Offermann 2014; Schober et al. 2014). Updating existing policies to cover e-cigarettes (and all electronic nicotine delivery systems) will eliminate the introduction of airborne toxins into enclosed spaces and establish a uniform standard for preventing the use of both combustible and electronic tobacco products in public and private spaces, including schools, offices, restaurants, bars, casinos, and airplanes.

Prohibiting the use of e-cigarettes in enclosed spaces eliminates potential health risks to nonusers and ensures their right to clean air; may discourage the dual use of electronic and combustible tobacco products; simplifies public compliance with and enforcement of existing clean indoor air laws; facilitates reduced consumption of these products; and maintains clear, comprehensive non-smoking norms (Richardson et al. 2014; World Health Organization 2014a). As of January 1, 2016, six states (Delaware, Hawaii, New Jersey, North Dakota, Oregon, and Utah) had passed comprehensive smokefree indoor air laws that include e-cigarettes (CDC 2015a). These laws prohibit smoking and the use of e-cigarettes in indoor areas of private worksites, restaurants, and bars. Sixteen additional states had prohibited the use of e-cigarettes on some or all state property, and 475 local laws restricted e-cigarette use in 100% smokefree venues (Americans for Nonsmokers’ Rights Foundation 2015). Nationwide, more than 400 local jurisdictions prohibit e-cigarette use in 100%-smokefree workplaces (Americans for Nonsmokers’ Rights Foundation 2015). Major cities that have addressed e-cigarettes include Austin, Boston, El Paso, Chicago, Los Angeles, Minneapolis, San Francisco, and New York City.

Prevent Youth Access

Ensuring that laws on youth access include e-cigarettes is intended to protect youth from exposure to nicotine, which can lead to addiction and other health problems. Additionally, ensuring that these laws include e-cigarettes helps to capture the full diversity of the tobacco product landscape, including combustible, non-combustible, and electronic tobacco products.

Effective strategies to deter access to e-cigarettes by youth and the use of these products in this population include restricting sales of e-cigarettes to minors, requiring verification of age, mandating clear signage about minimum age where sales take place, prohibiting the sale of e-cigarettes from vending machines, eliminating self-service displays of e-cigarettes, and actively enforcing existing laws with a focus on retailers. Compliance with laws that regulate the sale and distribution of e-cigarettes is facilitated by requiring retailers to be licensed. To date, 46 states have prohibited the sale of e-cigarettes to minors younger than a specified age (National Conference of State Legislatures 2015; The Council of State Governments 2015). Federally, aligning youth tobacco access control regulations with the statutory definition of tobacco products in the Tobacco Control Act, which includes e-cigarettes, could provide consistent framework to help ensure that restrictions on youth access to e-cigarettes are prioritized and enforced (*Federal Register* 2016). This could include modifications to the Synar regulation, which requires states, U.S. territories, and jurisdictions to enact and enforce laws prohibiting the sale or distribution of tobacco products to youth. Substance Abuse Prevention and Treatment Block Grant recipients must comply with the Synar amendment and implement regulations in order to receive their full awards (U.S. Food and Drug Administration, Center for Tobacco Products n.d.).

Licensing

Licensing is used to regulate professional practice and business operations and represents one strategy to control the rising use of e-cigarettes among youth. In general, in the case of tobacco-related licensing, a business is authorized to manufacture, distribute, or sell tobacco products as long as it complies with all relevant laws (McLaughlin 2010). Typically, tobacco-related licensing requirements for retailers and/or manufacturers help to prevent evasion of excise taxes, ensure that licensees comply with tobacco-related laws, and promote safe manufacturing practices (ChangeLab Solutions 2012). Repeat violators of relevant laws may be subject to suspension or permanent revocation of their license, an outcome that provides a strong incentive to comply with existing requirements. As in the conventional cigarette industry, licensing of e-cigarette retailers and manufacturers is designed in part to prevent the use of these products by youth and to facilitate safe manufacturing practices. Unlike traditional tobacco products, for which retailers sell prepackaged products and the number of manufacturers is limited, a growing number of businesses engage in both the retail sale and manufacturing of devices and liquids used in the devices (e-liquids). Stores devoted exclusively to the sale of e-cigarettes are known as “vape shops.” These shops frequently offer a social environment for using products, and they may also sell food and beverages (Sussman et al. 2014).

As of April 2015, 99 cities and counties in California required a retailer to obtain a license to sell e-cigarettes. The majority of these jurisdictions did so by broadening the definition of tobacco products to include “electronic smoking devices” (ChangeLab Solutions 2015a). The definition was purposely broadened to include products that do not include nicotine to decrease the complexity of enforcement and in recognition of the fact that e-cigarette devices are sometimes used with liquids that do not contain nicotine but may contain marijuana oil (The Center for Tobacco Policy & Organizing 2015a). Licensing requirements also may be used to restrict the sale of flavored products or to address issues of consumer and worker safety relative to the mixing of e-liquids.

Imposing a moratorium is another potential approach that has been used in some communities to stop new “vape shops” from entering the market while a more comprehensive approach was being considered. A moratorium is a land-use law that takes effect immediately to stop temporarily the issuance of a business license, building permit, or use permit. Typically, a moratorium is enacted to provide a jurisdiction with time to research and study how to regulate a type of business (ChangeLab Solutions 2015b). In California, several communities enacted moratoria that are initially 45 days but can be extended for up to 2 years (ChangeLab Solutions 2014, 2015b). A four-fifths vote, however, is required to establish a moratorium in California. Hayward and Union City, California, are examples of cities that have enacted moratoria and later adopted both retail licensing requirements for existing e-cigarette retailers and zoning restrictions to prohibit new vapor and hookah bars and lounges from opening within city limits (ChangeLab Solutions 2014; The Center for Tobacco Policy & Organizing 2015b).

Taxation and Other Price Policies

Taxation and other price policies directed at making e-cigarettes more expensive may be implemented at multiple levels of government, from local to federal. Increasing the price of conventional cigarettes, including those increases resulting from excise taxes, significantly prevents and reduces tobacco use, particularly among youth and young adults (USDHHS 2014), and has potentially more impact on prevalence of current use in this population than on first use (Bader et al. 2011). Similarly, price policies are likely to reduce the use of e-cigarettes: a 10% increase in the price of e-cigarettes has been estimated to reduce sales of disposable e-cigarettes by approximately 12% and reusable products by about 19% (Bader et al. 2011; Huang et al. 2014). Data are currently lacking on the potential effects that taxing e-cigarettes might have on conventional cigarettes. Tobacco products are taxed in two main ways:

- 1) A “specific” excise tax is levied based on the quantity of the product sold (e.g., as measured by number of cigarettes, weight, or volume). This type of mechanism applies the same tax across low-end and premium brands and is generally simple to administer. The disadvantages to specific excise taxes are that the real value of the tax declines over time with inflation, making products more affordable, and that super-lightweight products—such as snus, orbs, sticks, and dissolvables—are grossly under-taxed if the tax is based on weight (Freiberg 2012; Boonn 2013; Shang et al. 2015).
- 2) The second tax mechanism is an ad valorem excise tax, which is levied on a percentage of the value of the tobacco product (e.g., the retailer’s, wholesaler’s, or manufacturer’s price). This type of tax keeps up with inflation and establishes a flat tax rate across all brands, product types, weights, and packaging. The disadvantages to this kind of tax include the potential for tax evasion through predatory (below-cost) or anticompetitive pricing; increasing the price differential between products with different pretax prices, leading to greater price variability and more opportunity for tax avoidance; a government-provided subsidy for manufacturers’ price cuts; and more expensive brands being subjected to a larger tax (Freiberg 2012; Boonn 2013; Shang et al. 2015).

Table 5.2. Principle federal policies and regulations of tobacco that emphasize e-cigarettes

Agency	Authority and description	Current	Potential
Executive Office of the President (EOP) and Office of Management and Budget (OMB)	—	Executive Order 13058, issued on August 9, 1997 (EOP 1997), generally prohibits the smoking of tobacco products in all interior space owned, rented, or leased by the executive branch of the federal government, and in any outdoor areas under executive branch control in front of air intake ducts. The Executive Order carves out an exception to its smoking prohibition for any residential accommodation for persons voluntarily or involuntarily residing, on a temporary or long-term basis, in a building owned, leased, or rented by the federal government.	—
Executive Office of the President (EOP) and Office of the U.S. Trade Representative (USTR)	—	Executive Order 13193, issued January 18, 2001 (EOP 2001), prohibits all U.S. executive branch agencies from promoting the sale or export of tobacco. It also prohibits using U.S. trade initiatives to restrict tobacco marketing and advertising regulations in other countries, unless those regulations discriminate against U.S. tobacco products in favor of that country's domestic tobacco products.	—
Federal Communications Commission (FCC)	Has broad regulatory power over commercial communication, including television, radio, and the Internet.	15 U.S.C. § 1335 (the “Broadcast Ban”); 15 U.S.C. § 4402(f); Prohibits advertising for cigarettes, little cigars, smokeless tobacco, and chewing tobacco on radio, TV, or any other medium of electronic communication under FCC’s jurisdiction.	Prohibit the advertising of smoking accessories, cigars, pipes, pipe tobacco, or cigarette-making machines on television; prohibit the advertising of e-cigarettes on television; and regulate the advertising of tobacco products on the Internet.
General Services Administration (GSA)	In its role as an independent agency, GSA manages and maintains more than 1,550 federally owned buildings and leases space in an additional 7,100 buildings in the United States. GSA manages the federal government’s automobile fleet and is the acquisition arm of the federal government.	GSA Order ADM, 5800, 1C: Smoking in GSA-occupied space and government-owned or -leased vehicles assigned to GSA is prohibited “to protect GSA employees, GSA contractors, and the visiting public from exposure to tobacco smoke in the Federal workplace.” The Order prohibits smoking in or on all “interior GSA-occupied space, exterior GSA-occupied space, including courtyards, garages, loading docks, stairwells, rooftops and balconies, and other outdoor areas under GSA control within 25 feet of doorways and building air intake ducts; and government-owned or leased vehicles assigned to GSA” (U.S. General Services Administration 2009).	Clarify that existing policies include e-cigarettes. Implement a tobacco-free campus policy in GSA-occupied space.

Agency	Authority and description	Current	Potential
Office of Personnel Management (OPM)	—	While not regulatory in nature, OPM and GSA coordinate standard responses to frequently asked questions about the use of e-cigarettes in government facilities.	—
U.S. Department of Agriculture (USDA)	Commodity and inspection standards for agricultural products. Administers SNAP and WIC programs.	7 U.S.C. § 30: USDA provides commodity standards for tobacco. 7 U.S.C. § 2012: Under the <i>Food and Nutrition Act of 2008</i>, tobacco products cannot be purchased with SNAP benefits. ENDS are included in the policy because the USDA interprets ENDS to be tobacco products. 7 CFR 246.10: USDA identifies requirements for WIC-eligible foods.	—
U.S. Department of Defense (DoD)	May issue general instructions and restrictions in regulating the sale and/or use of tobacco products. Individual service branches may expand these regulations. Individual bases may also draft regulations. These typically are based on DoD instructions, directives, or service policies. DoD has authority over TRICARE.	DoD follows the smoking policy in federal facilities covered in 41 CFR 102-74.315, which states, “pursuant to Executive Order 13058, ‘Protecting Federal Employees and the Public From Exposure to Tobacco Smoke in the Federal Workplace’ it is the policy of the Executive Branch to establish a smokefree environment for federal employees and members of the public visiting or using federal facilities. The smoking of tobacco products is prohibited in all interior space owned, rented or leased by the Executive Branch of the federal government” (<i>Federal Register</i> 2008, p. 77518). Each of the armed services has issued statements clarifying that the prohibition on smoking tobacco products extends to the use of e-cigarettes. The 2015 NDAA directs the sale of cigarettes, cigars, and chewing tobacco at military commissaries. These items cannot be sold on military bases at prices lower than the most competitive prices in the local community. The NDAA replaced Directive 1330.09 (U.S. Department of Defense 2005), which established that tobacco prices on U.S. military bases should be no lower than 5% below the most competitive commercial price in the local community. Branches of the armed services have tobacco policies:	DoD-unified regulations on tobacco use in common housing. Increased restrictions on commissary sales.

Table 5.2. (Continued)

Agency	Authority and description	Current	Potential
		• U.S. Navy and Marines, Instruction 5100.13E (U.S. Navy 2002) • U.S. Army, Army Health Promotion Policy Regulation 600–63 (U.S. Army 1996) • U.S. Air Force, Instruction 40–102, Air Force Tobacco Policy (U.S. Air Force 2013) TRICARE covers limited tobacco cessation counseling from any TRICARE-authorized provider in the United States. This coverage includes up to 18 counseling sessions per quit attempt, with up to 4 individual counseling sessions per quit attempt. Two quit attempts per fiscal year are automatically covered, with coverage extending to a third with a doctor's justification and pre-authorization. TRICARE also covers tobacco cessation products, including prescriptions and over-the-counter products, with 120 days' use of a tobacco cessation product per quit attempt.	
U.S. Department of Education (ED)	Funding for tobacco control programs	In FY 2014, pursuant to 20 U.S.C. § 7131, <i>Safe and Drug-Free Schools and Communities Act</i>, ED awarded the first round of 5-year grant awards under the School Climate Transformation Grant—Local Educational Agency Grants program. These FY 2014, Year 1 grant awards provided more than \$35.8 million to 71 school districts in 23 states; Washington, DC; and the U.S. Virgin Islands. The funds should be used to develop, enhance, or expand systems of support for implementing evidence-based, multitiered behavioral frameworks for improving behavioral outcomes and learning conditions among students. The goals of the program are to connect children, youth, and families to appropriate services and supports; improve conditions for learning and behavioral outcomes for school-aged youth; and increase awareness of mental health issues and the ability to respond to such issues among school-aged youth. School districts can also use the funds to implement models for reform and evidence-based practices.	—

Agency	Authority and description	Current	Potential
		Drug prevention, including preventing tobacco use by youth, is an allowable activity. Grantees are encouraged, as part of their local needs assessment, to measure drug use among students along with other relevant issues and problems. This assessment of local needs will also be used by grantees to help identify and select the most appropriate evidence-based programs and practices. If the needs assessment indicates that drug abuse is an issue for students, prevention of drug abuse should be addressed by a multitiered behavioral framework.	
U.S. Department of Education (ED)	Restrictions on tobacco use	20 U.S.C. § 7181: <i>The Pro-Children Act of 2001</i> prohibits smoking in any indoor facility that provides routine or regular kindergarten, elementary, or secondary education and library, health, or day care services to children, if such services and/or facilities are funded by the federal government, whether directly or through state or local governments, by federal grant, loan, loan guarantee, or contract programs.	—
U.S. Department of Health and Human Services, Centers for Medicare & Medicaid Services (CMS)	Sets policies regarding Medicaid coverage for tobacco cessation products and counseling.	42 U.S.C. § 1396r-8(d)(7): Tobacco cessation medications cannot be excluded from coverage under Medicaid prescription drug benefits. Section 2502 of the <i>Affordable Care Act</i> amends section 1927(d)(2) of the <i>Social Security Act</i> by removing barbiturates, benzodiazepines, and agents used to promote smoking cessation from the list of drugs that a state Medicaid program may exclude from coverage or otherwise restrict.	—
U.S. Department of Health and Human Services, Centers for Medicare & Medicaid Services (CMS)	Sets policies regarding Medicaid coverage for tobacco cessation products and counseling.	42 U.S.C. §§ 18021(a)(1)(B), 18022(b)(1): Tobacco use screening and cessation must be provided at no cost as an essential health benefit and a preventive benefit. This includes Medicaid expansion plans, plans sold on insurance exchanges, and private plans. For youth: Tobacco cessation services are coverable as part of EPSDT, the Medicaid benefit for children and adolescents. EPSDT provides a comprehensive array of prevention, diagnostic, and treatment services for low-income infants, children, and adolescents under age 21, as specified in Section 19051 of the <i>Social</i>	

Table 5.2. (Continued)

Agency	Authority and description	Current	Potential
		<i>Security Act.</i> For pregnant women: Section 4107 of the <i>Affordable Care Act</i> amends section 1905 of the <i>Social Security Act</i> to require coverage of counseling and pharmacotherapy for cessation of tobacco use by pregnant women. Section 1905(bb)(2) of the <i>Social Security Act</i> defines the new tobacco cessation coverage services for pregnant women as services recommended in the 2008 PHS Guideline, or any subsequent modification of this Guideline, and such other services that the Secretary recognizes to be effective for cessation of tobacco use by pregnant women. <i>Affordable Care Act</i>, Section 4108, Medicaid Incentives for Chronic Disease Prevention Program: This is a grant program in which states apply for funds to incentivize Medicaid recipients to prevent chronic disease, including through tobacco cessation.	
U.S. Department of Health and Human Services, Centers for Medicare & Medicaid Services (CMS)	—	42 U.S.C. § 1395x (ddd): Medicare covers tobacco cessation programs (Centers for Medicare & Medicaid Services 2010); Effective for claims with dates of service on or after August 25, 2010, CMS will cover tobacco cessation counseling for outpatient and hospitalized Medicare beneficiaries: • Who use tobacco, regardless of whether they have signs or symptoms of tobacco-related disease; • Who are competent and alert at the time that counseling is provided; and • Whose counseling is furnished by a qualified physician or other Medicare-recognized practitioner.	—
U.S. Department of Health and Human Services, Centers for Medicare & Medicaid Services (CMS)		Intermediate and intensive tobacco cessation counseling services are covered under Medicare Parts A and B when the above conditions of coverage are met, subject to frequency and other limitations. Medicare covers two individual tobacco cessation counseling attempts per 12-month period. Each attempt may include a maximum of four intermediate or intensive sessions, with a total benefit covering up to eight sessions per 12-month period per Medicare beneficiary who uses tobacco. The practitioner	

Agency	Authority and description	Current	Potential
		and patient have the flexibility to choose between intermediate (more than 3 minutes, up to 10 minutes) and intensive (more than 10 minutes) cessation counseling sessions for each attempt. Medicare beneficiaries also have access to smoking cessation prescription medication through Medicare Part D.	
U.S. Department of Health and Human Services, Centers for Medicare & Medicaid Services (CMS)	Sets policies regarding private and marketplace health plan coverage of tobacco cessation products and counseling.	42 U.S.C. §§ 18021(a)(1)(B), 18022(b)(1): Tobacco cessation must be provided at no cost as an essential health benefit. This includes Medicaid expansion plans, plans sold on insurance exchanges, and private plans. 42 U.S.C. § 300gg-6 (Public Law 114-38): Tobacco cessation must be covered in employer plans. Plans should cover two cessation attempts per year, including (1) all FDA-approved cessation medications (both prescription and over-the-counter) and (2) four tobacco cessation counseling sessions, including telephone, group, and individual counseling. 42 U.S.C. § 300gg(a)(1)(iv): Tobacco users may be charged 50% more for insurance than nonusers of tobacco. 42 U.S.C. § 300gg-4(j)-(k): Employers may reward or penalize employees by up to 50% of the cost of health care coverage based on their tobacco use, if the employer offers a health-contingent wellness program designed to prevent or reduce tobacco use.	—
U.S. Department of Health and Human Services, National Institutes of Health (NIH)	NIH is a tobacco-free campus.	NIH's policy specifically includes e-cigarettes. In accordance with the tobacco-free initiative from HHS, the use of cigarettes, e-cigarettes, cigars, pipes, smokeless tobacco ("snuff"), and any other tobacco product is prohibited on the NIH campus in Bethesda, MD (NIH 2016).	—
U.S. Department of Health and Human Services, National Institutes of Health, National Institute on Drug Abuse (NIDA), National Advisory Council on Drug Abuse (NACDA)	The mission of NIDA is to advance science on the causes and consequences of drug use and addiction and to apply that knowledge to improve individual and public health. NACDA serves crucial roles in advising NIDA on research priorities and policy and in providing a secondary level of review for applications under consideration for federal funding.	NIDA (2016) urges grantees to recognize that: Receiving funding from the tobacco industry may compromise the perceived objectivity of their research results, which in turn could impact the overall credibility of their research findings, including its interpretation, acceptance, and implementation;	—

Table 5.2. (Continued)

Agency	Authority and description	Current	Potential
U.S. Department of Health and Human Services, Substance Abuse and Mental Health Services Administration (SAMHSA)		- Acceptance of tobacco industry funds is viewed by many as contributing directly or indirectly to the industry's interests, and thus harmful to the public health; and - Any connection between tobacco industry-supported research (or tobacco industry scientists) and NIDA could negatively impact NIDA's credibility and the public's trust in NIDA-funded research.	
U.S. Department of Homeland Security (DHS)	Implements the Synar Amendment, which requires states, in order to receive their full Substance Abuse Prevention and Treatment Block Grant awards, to enact and enforce laws that prohibit the sale or distribution of tobacco products to individuals under the age of 18. Sales and use restrictions for the U.S. Coast Guard. DHS Management Directorate-Directive No. 06603 Smoking Policy.	More information about the Synar Program is available online: http://www.samhsa.gov/synar/ about	SAMHSA is exploring opportunities to align the Synar regulation with the federal statutory definition of tobacco products, which includes e-cigarettes.
U.S. Department of Homeland Security (DHS), Bureau of Immigration and Customs Enforcement (ICE)	Issues standards for facilities housing immigration detainees	COMDTINST M6200.1B limits smoking to designated outdoor areas, prohibits use of tobacco by recruits, and prohibits tobacco use in any Coast Guard-controlled living quarters, including common areas. This policy includes extensive sales and advertising restrictions, but it does not consider NRT to be a tobacco product. Detainee smoking is prohibited in all buildings, including detainee-housing units. If smoking is permitted at a particular facility, the only designated smoking areas are outside of all buildings (Immigration and Naturalization Service 2000).	Implement a policy to enforce a ban on e-cigarette use on federal property.
U.S. Department of Housing and Urban Development (HUD)	Resident health in assisted housing	Public and Indian Housing (PIH) Notice 2009-21 strongly encourages HUD-funded public housing agencies to adopt smokefree policies in some or all of their public housing units. Housing Notice 2010-21 encourages owners and management agents of HUD-assisted multifamily housing to implement smokefree housing policies in	HUD's Office of PIH published its proposed rule on Instituting Smoke-Free Public Housing (80 FR 71762) on November 17, 2015, accepting comments through January 19, 2016 (<i>Federal Register</i> 2015). In addition to inviting comments on all aspects of the

Agency	Authority and description	Current	Potential
		one or all of the properties they own or manage. Both notices focus on cigarettes that “burn” as their mechanism for generating smoke, and so their applicability to e-cigarettes is uncertain. Regarding its Weaver Building headquarters (the only building for which GSA has designated HUD as the facility management authority), HUD follows GSA Order ADM 5800.1C: GSA’s smoking policy for federal offices (U.S. General Services Administration 2009). This GSA policy permits smoking in exterior space under GSA control that is beyond “25 feet of doorways and building air intake ducts,” except for “courtyards, garages, loading docks, stairwells, rooftops, and balconies.” The management of HUD’s other facilities, federally owned or leased, is not delegated to the Department, and so GSA makes the decision on smoking policy for those campuses.	proposed rule, the notice specifically solicited public comments on nine questions (e.g., should the policy extend to electronic nicotine delivery systems, such as e-cigarettes, and/or to waterpipe tobacco smoking?). Based on responses to HUD’s Request for Information on Adopting Smoke-Free Policies in PHAs and Multifamily Housing (77 FR 60712) (Federal Register 2012), HUD may consider drafting a regulation or notice that could prohibit smoking in some or all HUD-assisted multifamily housing. Such a proposal could cover e-cigarettes. HUD is beginning to prepare for the adoption and implementation of a campus-wide tobacco-free policy, which would include e-cigarette use, at the Weaver Building headquarters by January 1, 2017.
U.S. Department of Justice, Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF)	ATF is given primary jurisdiction to combat cigarette trafficking and administration (via the CCTA) and to stop tobacco diversion (via the PACT).	18 U.S.C. § 2342: Under the CCTA, it is illegal to possess more than 10,000 unstamped cigarettes in a state that requires a tax stamp. 18 U.S.C. § 2343: Any person who distributes more than 10,000 cigarettes must keep accurate records pertaining to the shipment, receipt, sale, and distribution of cigarettes. 18 U.S.C § 2320: Trafficking in counterfeit cigarettes. 15 U.S.C. § 375: It is illegal to ship cigarettes to a non-licensee in a state without notifying the state taxation authority. 15 U.S.C. § 375–377: Requires online retailers to check the identification of customers at purchase and delivery: section 375 covers definitions; section 376 covers reports to state tobacco administrators; and section 377 covers penalties. The <i>Smuggled Tobacco Prevention (STOP) Act</i> amends the IRC to restrict the sale, lease, export or import, or delivery of tobacco production machines to persons lawfully engaged in (1) the sale, lease, export or import, or delivery of such machines; (2) the manufacture or packaging of tobacco products or processed tobacco; or (3) the application of unique identification markings onto tobacco products or processed tobacco packages.	—

Table 5.2. (Continued)

Agency	Authority and description	Current	Potential
U.S. Department of Justice, Bureau of Prisons (BOP)	BOP has authority to govern the control and management of federal penal and correctional institutions.	28 C.F.R. § 551.162: Smoking is generally prohibited in and on the grounds of BOP institutions and offices, with exceptions for smoking as part of an authorized inmate religious activity, and for smoking only in smoking areas designated by the warden, for BOP staff and official visitors. 28 C.F.R. § 551.163: Possession of smoking apparatus and tobacco in any form is prohibited for inmates, unless as part of an authorized inmate religious activity.	BOP Operations Memorandum 006-2015 (BOP 2015) sets out guidelines for e-cigarette use. (Guidelines state that e-cigarette use is to be limited to designated outdoor areas that are reasonably accessible to employees and provide a measure of protection from the elements. These areas may only be used by employees, but must be separate from the areas presently designated as “smoking areas” for use of tobacco products. Indoor use of e-cigarettes shall not be permitted in BOP facilities, except in perimeter towers and perimeter patrol vehicles when occupied by one person.
U.S. Department of Labor, Occupational Safety and Health Administration (OSHA)	Sets standards for indoor air quality.	29 CFR 1910.1000, Air Contaminants: This policy restricts employee exposure to several of the main chemical components found in tobacco smoke. OSHA rules apply to tobacco smoke only in rare and extreme circumstances, such as when contaminants created by a manufacturing process combine with tobacco smoke to create a dangerous air supply that fails OSHA standards for the workplace. In normal situations, exposures would not exceed permissible exposure limits and, as a matter of prosecutorial discretion, OSHA will not apply the General Duty Clause to environmental tobacco smoke.	Have smokefree workplaces. In the 1990s, OSHA proposed a regulation setting indoor air quality standards for environmental tobacco smoke, but this rulemaking was terminated (<i>Federal Register</i> 2001).
U.S. Department of Transportation (DOT)	Sets restrictions on tobacco use on commercial and personal aircraft.	49 U.S.C. § 41706: Prohibits smoking on passenger flights. 14 CFR Part 252: DOT rule implementing 49 U.S.C. § 41706, and prohibiting smoking on most passenger flights. DOT interprets current Part 252 to include e-cigarettes in smokefree policies. Note: FAA regulations also prohibit smoking on most aircraft from an aircraft safety perspective, not from a health perspective (see notes to 14 CFR Part 252).	In early 2016, DOT issued a final rule (RIN 2105-AE06). In keeping with section 41706, the rule amends Part 252 to prohibit smoking on charter flights where a flight attendant is a required crew member. The rule also makes explicit the determination that the use of e-cigarettes falls within the definition of smoking. DOT’s Pipeline and Hazardous Materials Safety Administration has proposed a rule to prohibit the carrying of e-cigarettes in an aircraft cabin, and to prohibit stowage of e-cigarettes in the cargo hold of an aircraft (this is a hazardous material/safety rule, not a health/tobacco rule).

Agency	Authority and description	Current	Potential
U.S. Department of Treasury, Alcohol and Tobacco Tax and Trade Bureau (TTB)	TTB administers the provisions of the Internal Revenue Code (IRC) of 1986, as amended, that impose federal excise taxes on tobacco products and cigarette papers and tubes, and it establishes a comprehensive civil and criminal framework to protect the revenue. Among other issues, TTB investigates illegal production, underreporting of production, smuggling or unlawful importation, and diversion of domestic tobacco products intended for export.	26 U.S.C. 26 § 5701–5763, Tobacco Products and Cigarette Papers and Tubes: Under the IRC, the tobacco products that are subject to tax and TTB regulation are cigars, cigarettes, smokeless tobacco (chewing tobacco and snuff), pipe tobacco, and roll-your-own tobacco. Each of these tobacco products is defined with reference to “tobacco.” TTB also has regulatory authority over processed tobacco, which is not subject to tax. TTB regulations define processed tobacco to mean any tobacco that has undergone processing but that does not include tobacco products. The processing of tobacco includes, but is not limited to, stemming (i.e., removing the stem from the tobacco leaf); fermenting, threshing, cutting, or flavoring the tobacco; or otherwise combining the tobacco with nontobacco ingredients. To protect revenue, the IRC and its implementing regulations establish qualification criteria to engage in businesses related to manufacturing, importing, or exporting tobacco products or in manufacturing or importing processed tobacco, and they require that persons obtain permits to engage in these activities.	TTB will collaborate with foreign-counterpart tax administrators to share information and best practices in the administration of tobacco excise taxes and their enforcement. Areas of possible technical assistance include setting up an auditing system and permitting regimen and conducting investigations. TTB’s tobacco laboratory provides technical assistance to TTB program offices on tobacco products for regulatory compliance and enforcement purposes. TTB’s tobacco laboratory develops and validates analytical methods and protocols on tobacco products. It also collaborates with national and international tobacco regulatory federal agencies and has established a collaborative partnership with the World Health Organization’s Tobacco Laboratory Network and the North America Tobacco Regulatory Laboratory Network.
U.S. Department of Treasury, Alcohol and Tobacco Tax and Trade Bureau (TTB)		Under the IRC, manufacturers of tobacco products and export warehouse proprietors must file a bond that relates to the tax liability for the tobacco products on the premises covered by the permit. The IRC and implementing regulations also include recordkeeping and reporting requirements designed to ensure that TTB can verify that the tax on tobacco products is paid or determined or that adequate documentation exists to confirm that a tax exemption applies. The IRC also provides TTB with certain enforced-collection options (e.g., liens and levies), civil and criminal penalties, permit suspension and revocation procedures, and forfeiture provisions to ensure that the tax is collected. ENDS that do not contain nicotine derived from tobacco are not tobacco products under the IRC and are not subject to taxation or TTB regulation. ENDS containing nicotine derived from tobacco may meet the definition of a tobacco product under the IRC, in which case they would be regulated by TTB and taxed accordingly.	

Table 5.2. (Continued)

Agency	Authority and description	Current	Potential
U.S. Department of Veterans Affairs (VA)	Can restrict the use of e-cigarettes and combustible cigarettes on facility grounds of the Veterans Health Administration to designated outdoor smoking areas only.	Public Law 102-585: Requires medical centers, nursing homes, and domiciliary care facilities of the Veterans Health Administration to establish smoking areas for patients and residents in a way that is consistent with medical requirements and limitations.	Include language about restrictions on the use of e-cigarettes in local and national guidance regarding smokefree policies.
U.S. Department of Veterans Affairs (VA)	Provides evidence-based tobacco cessation treatment to veterans receiving care in the VA health care system.	38 CFR Part 17: Eliminated in 2006 the copayment for smoking cessation counseling for veterans in care facilities of the Veterans Health Administration (<i>Federal Register</i> 2006).	Continue to provide clinical guidance for the health care professionals and patients in facilities of the Veterans Health Administration on the evidence base of (a) potential health effects of e-cigarettes and (b) comparisons to FDA-approved NRT for cessation treatment.
U.S. Environmental Protection Agency (EPA)	Sets policies regarding the hazardous waste status of e-cigarettes under the RCRA.	Nicotine is a commercial chemical product listed in 40 CFR 261.33(e) and is an acute hazardous waste (EPA waste code P075) when disposed. EPA has concluded that nicotine is the sole active ingredient of the e-liquid in e-cigarettes and thus a commercial chemical product, that e-cigarettes are not manufactured articles, and that e-cigarette cartridges are considered containers of nicotine. Therefore, e-cigarettes may be regulated as acute hazardous waste code P075 when disposed.	—
U.S. Environmental Protection Agency (EPA)		If the nicotine e-liquid is legitimately recycled, it is not considered a solid waste under 261.2 because it is considered a commercial chemical product, and therefore it is not subject to hazardous waste regulation. E-cigarettes that are disposed of by consumers at their residences are considered exempt household hazardous waste under 261.4(b)(1) and are not subject to regulation as hazardous waste under the federal RCRA regulations. - Regulatory Citation(s): 261.2, 261.4(b)(1), 261.33. - Statutory Citation(s): 3006 Read U.S. Code 42, Chapter 82.

Governments use uniform, tiered, and mixed-tax approaches to implement specific and ad valorem tobacco excise taxes. Uniform systems apply the same tax rate across all products; tiered systems levy taxes based on such product characteristics as toxicity, nicotine content, type of production (handmade versus machine made), sales volume, packaging, or whether the products are domestic or imported; and mixed systems use a combination of uniform and tiered-tax approaches (Shang et al. 2015). Tiered-tax approaches, such as those based on nicotine content, could steer consumers to a less toxic product or one with lower nicotine (Benowitz 2014). Tiered-tax approaches are more complex to administer and may provide greater opportunity for tax evasion as a result of manipulation of the product or its packaging by the manufacturer (Shang et al. 2015). In recognition of nicotine's toxicity, particularly to youth, several health groups have endorsed imposing excise taxes on e-cigarettes to discourage their use by youth (American Thoracic Society 2013; Association of State and Territorial Health Officials 2014; Bhatnagar et al. 2014; Brandon et al. 2015a; Crowley and Health Public Policy Committee of the American College of Physicians 2015; National Association of County and City Health Officials 2014). E-cigarettes are likely less toxic than combustible products (such as conventional cigarettes), and therefore, some contend should be taxed at a lower rate (Benowitz 2014; Bhatnagar et al. 2014). Yet others argue that e-cigarettes should be taxed at the same rate as other tobacco products (Freiberg 2012; American Thoracic Society 2013; National Association of County and City Health Officials April 2014).

As of January 2016, four states (Kansas, Louisiana, Minnesota, and North Carolina) and six localities (Juneau, Matanuska-Susitna, Petersburg, and Sitka, Alaska; Montgomery County, Maryland; and Chicago, Illinois) had enacted e-cigarette taxation policies. Minnesota's ad valorem tobacco tax equates to 95% of the wholesale cost of any product containing or derived from tobacco (Minnesota Revenue 2014; Tobacco Control Legal Consortium 2015). It taxes e-liquids and e-cigarettes sold with nicotine cartridges that cannot be removed (i.e., disposables). In Minnesota, devices without a nicotine cartridge are not taxed as a tobacco product. On the other hand, North Carolina applies a specific excise tax, taxing e-liquids based on volume at 5 cents per milliliter (National Conference of State Legislatures 2015).

The Tobacco Control Legal Consortium, which is based at William Mitchell College of Law in St. Paul, Minnesota, recommends using an ad valorem tax for e-cigarettes applied at the retail level to the "essential" components of these devices. The tax is simple, captures both disposable and refillable devices, and could exclude accessories and universal parts sold separately, such as batteries or charging cords (Tobacco Control Legal Consortium 2015).

Numerous major health organizations support raising the price of e-cigarettes through non-tax options, such as limiting rebates, discounts, and coupons (Freiberg 2012; Association of State and Territorial Health Officials 2014; Bhatnagar et al. 2014; Huang et al. 2014; Brandon et al. 2015a).

Finally, Chaloupka and colleagues (2015) have proposed that differential taxation of tobacco products can be used to incentivize a move away from combustible products to less hazardous noncombustible products, including e-cigarettes. They have argued that taxation could be part of a harm-reduction system. In their view, future determinations by FDA as to whether a product poses a substantially reduced risk would be one criterion in determining the relative rate of taxation.

Restrictions on Marketing

As described in Chapter 4, the marketing of e-cigarettes drives consumer demand for these products. Such marketing also may promote misperceptions about the safety and efficacy of these products for use as cessation devices (Choi and Forster 2014; Mark et al. 2015; Pokhrel et al. 2015). For some populations—such as pregnant women, adolescents, former smokers, and young adults—the adverse health consequences of nicotine intake are substantial. Several groups have supported extending marketing restrictions that apply to conventional cigarettes and other tobacco products to e-cigarettes (Association of State and Territorial Health Officials 2014; Bam et al. 2014; Bhatnagar et al. 2014; Partnership for Prevention 2014; Brandon et al. 2015a). Significant barriers still exist to regulating commercial speech, including the First Amendment rights of the e-cigarette companies (Laird-Metke 2010).

Additionally, for traditional tobacco products, partial advertising bans and voluntary agreements have generally been ineffective in reducing consumption because the tobacco industry circumvents the restrictions by shifting the marketing platforms used to unregulated platforms (National Cancer Institute 2008). This response would be expected to be similar with regard to e-cigarettes. Therefore, despite the numerous barriers, public health groups and state, local, tribal, and territorial governments should take steps to stem the proliferation of e-cigarette marketing likely to appeal to young people by using tools designed to curb youth-oriented tobacco marketing and expanding evidence to inform future restrictions on the marketing of e-cigarettes to youth and young adults.

Surveillance of e-cigarette marketing, performing content analyses of the messages used, and conducting studies to assess the link between exposure to e-cigarette marketing and the use of e-cigarette products, particularly among youth and young adults, will facilitate the development of an evidence base of the type that informed prior federal and Master Settlement Agreement restrictions on tobacco advertising. Observations of retailers' practices, assessments of outdoor advertising, and identification of event sponsorships and promotional activities at bars and community events are actions that state, local, tribal, and territorial public health agencies have taken related to traditional tobacco products. Many of these actions can be adapted to monitor and document the presence of e-cigarette marketing in communities (Pucci et al. 1998; Feighery et al. 2001; Rigotti et al. 2005; Roeseler et al. 2010; Rose et al. 2014).

In the absence of legal restrictions on e-cigarette marketing, and apart from the issue of the previous promulgation by some companies of unsubstantiated health and cessation claims, public health groups can advocate for television and radio broadcasters, print and outdoor media companies, the management of event venues and sports events, digital media outlets, retailers, and others to voluntarily refuse to air or place e-cigarette advertising, offer sponsorships, or give out free samples at fairs and festivals. Although the impact of a voluntary approach may be low, such actions raise awareness, build concern, and help to denormalize the proliferation of e-cigarette marketing. In California, surveillance plus voluntary efforts to promote restrictions on sponsorship of events by the tobacco industry facilitated a modest decline in tobacco industry-sponsored events and youth-oriented activities at those events that promoted the interests of the tobacco companies, and it led to a productive partnership with the tobacco litigation unit of the California attorney general's office that resulted in several settlements with tobacco companies (Roeseler et al. 2010).

State, local, tribal, and territorial public health agencies may be able to contribute to the stimulation of enforcement and compliance with existing rules that constrain marketing. Some states have brought lawsuits against e-cigarette companies, alleging that distributors of these products violated state law by selling to minors or making unsubstantiated health claims; some of those lawsuits resulted in financial damages and agreements to stop making claims that e-cigarettes are safer than conventional cigarettes unless confirmed by rigorous science (Center for Public Health and Tobacco Policy 2013).

Finally, another area to address is the use of “advertorials” employed by e-cigarette retailers to promote cessation and health claims. Advertorials are paid advertisements designed to look like an independent editorial. Although there are no specific rules for how a publisher should distinguish actual editorial content from paid editorial content in terms of their appearance, the Federal Trade Commission (FTC) stated in an advisory opinion that disclosure of the source is necessary when content “uses the format and has the general appearance of a news feature and/or article for public information which purports to give an independent, impartial and unbiased view” (*Federal Register* 1972, p. 154). Additionally, paid advertising must be disclosed clearly and conspicuously in a manner that is understandable to consumers (FTC 1984). State and local public health agencies can play an important role by monitoring and providing substantiation to their state attorney general or FTC regarding advertising that makes improper claims or is not clearly identified as advertising.

Educational Initiatives

The extensive data reviewed in Chapter 2 highlighted the limited knowledge that members of the general public, particularly adolescents and young adults, have about e-cigarettes and their potential for nicotine addiction and other adverse health consequences. FDA has jurisdiction for product warnings that can reach users, but that agency, along with other federal entities and state and local governmental and nongovernmental organizations, can also carry out educational campaigns to enhance such limited knowledge levels. Potentially effective initiatives with youth and young adults to prevent smoking were reviewed in the 2012 Surgeon General’s report and may be applicable to preventing e-cigarette use. That report concluded that sufficient evidence exists to conclude that mass media campaigns, comprehensive community programs, comprehensive statewide tobacco control programs, and school-based programs that have shown evidence of effectiveness, if they contain specific components, can produce at least short-term effects and reduce the prevalence of tobacco use among school-aged youth (USDHHS 2012).

Implications for Health Care Practice

Although the issues are not well documented, health care practitioners face questions about e-cigarettes from their patients and their communities, including what are the risks of using e-cigarettes, how do these risks compare with those of cigarettes or other combustible products, and is e-cigarette use an effective way to quit smoking? Chapter 3 set out the limited evidence base related to these questions. Clinicians need to respond to these questions and guide their patients in the context of considerable uncertainty. At this time, practitioners can turn to the various statements from medical organizations, which generally urge caution regarding e-cigarettes and do not find the evidence to be supportive of their use for cessation or for formal harm-reduction strategies (Table 5.3). In fact, any recommendation to use

Table 5.3. Medical organizations
A. Positions of professional organizations

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
American Academy of Pediatrics (2015b)	—	• “Concentrated nicotine solution for electronic nicotine delivery systems should be sold in child-resistant containers with amounts limited to that which would not be lethal to a young child if ingested.” • “Prohibitions on smoking and use of tobacco products should include prohibitions on use of electronic delivery systems.”	• “The promotion and sale of electronic nicotine delivery systems to youth should be prohibited by federal, state, and local regulations.” • “Prohibitions on promotion should include all media that can be viewed by youth, including broadcast, print, and electronic (Web- or Internet-based) media.” • “Prohibitions on promotion should include prohibitions on sponsorships, such as sports, cultural event, and entertainment sponsorships. Any promotional activities that can be accessed by children and/or adolescents should be considered promoting to children.” • “Electronic nicotine delivery systems should be subject to the same restrictions on advertising and promotion at least as restrictive as that on combustible cigarettes. Until government agencies institute these prohibitions, media companies, entertainment companies, sports teams, and promoters should voluntarily institute these prohibitions.” • “Celebrities should not use their privileged position to model tobacco product use, including electronic nicotine delivery systems and other existing or emerging tobacco products.”	—

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
American Association for Cancer Research (AACR) and the American Society of Clinical Oncology (2015)	- FDA has not approved e-cigarettes as smoking cessation aids, and current data are inconclusive with regard to their efficacy as quit-smoking products. “Oncologists would be wise to refrain from recommending e-cigarettes to patients as a first-line therapy for smoking cessation.”	“The evidence regarding the risks and benefits of e-cigarettes is difficult to interpret, and data on the long-term consequences of e-cigarette use are not yet available.” “Chemicals and ultrafine particles known to be toxic and carcinogenic and/or to cause respiratory and heart distress have been identified in e-cigarettes.” “Studies find the levels of the toxicants in e-cigarette aerosol to be significantly lower than in cigarette smoke and, in many cases, comparable with trace amounts found in a medicinal nicotine inhaler. It is unclear what effects these toxicants might have on e-cigarette users after chronic and frequent use.” “The vast majority of e-cigarette users use products containing nicotine.” - Nicotine is an addictive chemical, adversely affects maternal and fetal health during pregnancy, has adverse consequences for fetal brain development, and may adversely affect the adolescent brain. It is unclear what effect nicotine intake via e-cigarettes has on health or on the addictiveness of these products.” “Data from the [CDC] showed a significant increase in e-cigarette-related calls to poison centers between 2010 and 2014 as a result of accidental ingestion or absorption of e-cigarette liquid.”	“The FDA CTP should regulate all ENDS that meet the statutory definition of tobacco products and their component parts. ENDS delivery systems and e-liquids containing tobacco-derived nicotine should be regulated whether they are sold together or separately.” “ENDS manufacturers should be required to register with FDA and report all product and ingredient listings, as well as the nicotine concentration in the ENDS solution.” “ENDS packaging and advertising should be required to carry health warnings and safety labels—including a warning regarding nicotine addiction.” “Youth-oriented ENDS advertising and marketing should be prohibited, including: self-service ENDS displays, the provision of gifts and other giveaways with purchase of ENDS, the sale and distribution of items such as hats or t-shirts with ENDS brand logos, brand name sponsorship of social or cultural events, or of any team entry into those events, and youth-oriented advertising of tobacco products.” “Internet and other mail-order sellers of ENDS should be required to check the age and identification of customers at the point of purchase and delivery; to comply with all laws in the purchaser’s state or local jurisdiction; and pay all applicable federal, state, and local taxes.”	“There are insufficient data on health consequences of e-cigarette use, their value as tobacco cessation aids, and their effects on the use of combustible tobacco products by smokers and nonsmokers. “Oncologists should advise all smokers to quit smoking combustible cigarettes, encourage use of FDA-approved cessation medications, refer patients for smoking cessation counseling, and provide education about the potential risks and lack of known benefits of long-term e-cigarette use.”

Table 5.3. (A. Continued)

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
(Continued)		• “Secondhand exposure to toxicants and nicotine from e-cigarette aerosol has been documented, though there are not current data suggesting that exposure to the aerosol has adverse health effects.” • “There are no published studies evaluating thirdhand (i.e., residue that builds up on surfaces over time) exposure to e-cigarette aerosol in indoor environments, although preliminary data suggest that nicotine from e-cigarettes can stick to surfaces.”	• “Childproof caps should be required for all e-liquid containers.” • “ENDS and ENDS liquid containing candy and other youth-friendly flavors should be banned unless there is evidence demonstrating that these products do not encourage youth uptake.” • “ENDS use should be prohibited in places where combustible tobacco product use is prohibited by federal, state, or local law until the safety of second- and thirdhand aerosol exposure is established.” • “Funding generated through tobacco product taxes, including any potential taxes levied on ENDS, should be used to help support research on ENDS and other tobacco products, but should not preclude the allocation of federal funding for this research.” • “All data related to ENDS composition, use, and health effects should be disclosed for dissemination and independent review as well as to enhance policy decisions for ENDS product regulation.” • “Tobacco products should be taxed proportionate to their harm; therefore, ENDS should not be taxed at equal or higher rates than combustible cigarettes.” • “State and local governments should implement ENDS regulations within their authorities that are appropriate for protecting the public health, including restricting the sale, distribution, marketing, and advertising of ENDS to youth.” • “International cooperation is needed to develop standards for the regulation of ENDS, and these regulations should prioritize protection of the public’s health and draw upon the best available scientific evidence whenever possible.”	—

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
American Association for Respiratory Care (AARC) (2015)	“Even though the concept of using the e-cigarettes for smoking cessation is attractive, they have not been fully studied and the use among middle school children is increasing year after year.”	“There is no evidence as to the amount of nicotine or other potentially harmful chemicals being inhaled during use or if there are any benefits associated with using these products.”	—	- Date effective: April 2014 “The [AARC] opposes the use of the electronic cigarette (e-cigarette).”
American College of Physicians (ACP) (Crowley and Health Public Policy Committee of the ACP 2015)	“ENDS, which include electronic cigarettes, or e-cigarettes, are growing in popularity, but their safety and efficacy as a smoking cessation aid are not well understood.”	“[There is concern] that the health effects of ENDS use are unknown, that they may appeal to young people, and that they may encourage dual use of ENDS and traditional tobacco products.”	“The Food and Drug Administration [should] extend its regulatory authority granted through the <i>Family Smoking Prevention and Tobacco Control Act</i> to cover electronic nicotine delivery systems (ENDS).” “Characterizing flavors should be banned from all tobacco products, including ENDS.” “The [ACP] supports taxing tobacco products, including ENDS devices and nicotine liquids, to discourage use among children and adolescents. Local governments should be permitted to establish higher tax rates for ENDS and related products than state levels.” “The [ACP] supports legislative or regulatory efforts to restrict promotion, advertising, and marketing for ENDS products in the same manner as for combustible cigarettes, including a prohibition on television advertising.” “Youth tobacco prevention efforts, such as antismoking media campaigns and school-based interventions, should include information about the potential risks of ENDS use.” “The federal, state, and local regulators should take action to extend indoor and public place clean air laws that prohibit smoking in public places, places of employment, commercial aircraft, and other areas to ENDS products.”	“The [ACP] supports strong regulations to ensure product safety and transparency, policies that prevent use among young people, increased research to better determine their health effects, strong limits on marketing and promotion to discourage interest among young people, and application of indoor air laws to protect the health of bystanders.” “This paper is not intended to offer clinical guidance or serve as an exhaustive literature review of existing ENDS-related evidence but to help direct the [ACP], policymakers, and regulators on how to address these products.”

Table 5.3. (A. Continued)

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
(continued)			“The federal government should authorize and appropriate funding to rigorously research the health effects of ENDS use, chemical content, and toxicity; effects of ENDS vapor exposure; dual-use rates; and effects of ENDS-derived nicotine on human health.”	
American Thoracic Society (2013, 2015)	“The new CDC data show that Big Tobacco is once again peddling a new product intended to get youth hooked on nicotine, and that e-cigarettes are not about harm reduction or smoking cessation, but about addiction.”	“The short- and long-term health risks of these nicotine-delivery devices are largely unknown.”	“States should regulate e-cigarettes as tobacco products. - E-cigarettes should not be sold to those younger than 18, and regulations requiring identification and proof of age at the time of purchase should apply. Internet sales of e-cigarettes should be strictly regulated.” “E-cigarettes should be taxed at rates equivalent with traditional cigarettes and other tobacco products.” “E-cigarettes should be subject to the same restrictions regarding public use as combustible tobacco products, and e-cigarettes should not be used in smoke-free areas.” “The FDA should deem regulatory authority over e-cigarettes.” “Candy and menthol flavored e-cigarettes should be banned.” “E-cigarette packaging should include warning labels, similar in size and scope to those required of combustible tobacco packaging. Where risks are known, the consumer should be informed of those risks in clear and direct language. Where data regarding risk is [sic] unavailable or inconclusive, the consumer should be informed of the lack of reliable safety testing data.”	“[E]-cigarettes need to be subject to the same marketing and manufacturing restrictions as tobacco products.” “For the first time, e-cigarette use among young people is higher than for any other tobacco product.”

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
(continued)			• “The FDA should regulate the form and content of e-cigarette advertising.” • “Both direct and implied health and safety claims by e-cigarette manufacturers should be subject to the same evidentiary review process currently required for other products making such claims.” • “The FDA should require e-cigarette manufacturers to adopt Good Manufacturing Processes similar to those that exist for other regulated products, including lot numbers, securing packaging, etc.” • “Given that nicotine is an addictive drug, with the dependence liability related to the pharmacokinetic characteristics of the delivery device, delivery characteristics of the e-cigarette should be evaluated and disclosed, and periodically monitored to ensure consistency of the product’s dependence potential over time.”	
American Thoracic Society (2013, 2015)	—	—	• Content of e-cigarette cartridges should be disclosed and regulated. • “The nicotine content of the e-cigarette cartridge should not exceed that of similar user volume of combustible tobacco.” • “Deliverable nicotine levels should be consistent between cartridges.” • “Researchers and clinicians, along with scientific societies and publications, receiving funding from e-cigarette manufacturers should disclose this relationship and the potential for conflict of interest in a manner equivalent to disclosures required for funding from the remainder of the tobacco industry.”	—

Table 5.3. (A. Continued)

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
European Respiratory Society (ERS) (2014)	“Electronic cigarettes are designed for the purpose of direct nicotine delivery to the respiratory system, and they fall into a regulatory gap in most countries, escaping regulation as medicinal products and avoiding the controls applicable to tobacco products.”	“For ERS, the priority of the Revision of the Tobacco Products Directive is to protect children and youth from becoming smokers by preventing them from picking up their first cigarette.” “There is no adequate scientific research available on the overall health risk or the long-term effects of electronic cigarette use on humans.”	“Mandatory reporting system of ingredients used in tobacco products.” “Harmonised regulation of the ingredients of tobacco products.” “80% pictorial health warnings, covering the front and back of packages. Based on evidence, the larger the pictorial health warnings are, the more effective they are.” “Plain/standardised packaging of tobacco products.” “Introduction of both visible and invisible security features on tobacco packaging and ensuring that the storage and access to such data is [sic] independent from tobacco companies.” “Prohibition on the cross-border distance sale of tobacco products.” “Strong regulatory framework and independent research for electronic cigarettes. Any regulation of electronic nicotine delivery systems should be science based.” “Ensuring the adoption of delegated acts is not exposed to the interests of the tobacco industry, which would jeopardise the achievement of high level of health protection.”	“ERS supports the European Commission’s Proposal for the Tobacco Products Directive and Rapporteur Linda McAvan’s efforts to improve it.” “Introduction of standard packs with increased health warnings.” “Prohibition of characterizing flavours.” “Strengthening of traceability and security features for combating illicit trade.” “Prohibiting misleading features, including slim cigarettes.” “Approximately 700,000 EU citizens die prematurely every year because of tobacco consumption.”
Forum of International Respiratory Societies (American College of Chest Physicians 2014; Schraufnagel et al. 2014)	“Studies looking at whether electronic cigarettes can aid smoking cessation have had inconsistent results.”	“The safety of electronic cigarettes has not been adequately demonstrated.” “The addictive power of nicotine and its untoward effects should not be underestimated. “Potential benefits to an individual smoker should be weighed against harm to the population of increased social acceptability of smoking and use of nicotine.” “Adverse health effects for third parties exposed to the emissions of electronic cigarettes cannot be excluded.”	“Health and safety claims regarding electronic nicotine delivery devices should be subject to evidentiary review.” “If ENDS devices are permitted, they should be regulated as tobacco products.” “Research, supported by sources other than the tobacco or electronic cigarette industry, should be carried out to determine the impact of electronic nicotine delivery devices on health in a wide variety of settings.” “The use and population effects of END devices should be monitored.” “All information derived from this research should be conveyed to the public in a clear manner.”	“ENDS should be restricted or banned, at least until more information about their safety is available.”

Table 5.3. (Continued)
B. Voluntary Health Organizations

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
American Cancer Society (ACS) (2014)	“Because the American Cancer Society doesn’t yet know whether e-cigarettes are safe and effective, we cannot recommend them to help people quit smoking.” “There are proven methods available to help people quit, including pure forms of inhalable nicotine as well as nasal sprays, gums, and patches.”	“[E]-cigarettes are not labeled with their ingredients, so the user doesn’t know what’s in them.” “Inhaling a substance is not the same as swallowing it.” “Studies have shown that e-cigarettes can cause short-term lung changes that are much like those caused by regular cigarettes.”	“E-cigarettes need to be researched and regulated.”	“Until electronic cigarettes are scientifically proven to be safe and effective, ACS will support the regulation of e-cigarettes and laws that treat them like all other tobacco products.”
American Heart Association (AHA) (Bhatnagar et al. 2014)	“Current evidence evaluating the efficacy of these products as a cessation aid is sparse, confined to 2 randomized controlled trials and 1 large cross-sectional study, anecdotal reports, and Internet-based surveys.” “[R]eports are confounded by a self-selection bias in that the respondents are often e-cigarette enthusiasts.” “The AHA maintains that e-cigarette use should be part of tobacco screening questions incorporated into clinical visits and worksite/community health screenings that are tied into healthcare delivery.” “Clinicians should be educated about e-cigarettes and should be prepared to counsel their patients who are using combustible tobacco products to use e-cigarettes as a primary cessation aid.” “For patients with existing cardiovascular disease and stroke, or at risk of a cardiovascular disease event, intensive cessation counseling should be offered as soon as possible.”	“Low levels of harmful or potentially harmful metals such as lead, nickel, and chromium are listed as having been detected.” “Trace levels of tobacco-specific N-nitrosamines, polycyclic aromatic hydrocarbons, and volatile organic compounds in the e-liquid and vapor have been reported.” “The FDA has issued warnings to several e-cigarette companies for selling e-cartridges with [diethylene glycol, weight-loss chemical rimonabant (Zimulti), and the erectile dysfunction medication tadalafil (active ingredient in Cialis)] contaminants.” “There are no reports of e-cigarette safety in patients with known cardiovascular disease.”	“The regulation should allow for quality-controlled products for adults who want to transition from conventional cigarettes to e-cigarettes or to quit or reduce smoking.” “Bottles containing nicotine refill liquids can be toxic if swallowed, so cartridges and bottles should have proper warning labeling and child-proofing packaging.” “It is important that the relevant government agency monitor whether these devices are used for delivery of other drugs and medications.”	“The [AHA] supports effective regulation that addresses marketing, labeling, quality control of manufacturing, and standards for contaminants.” “[It] also supports including e-cigarettes in smoke-free air laws and prohibiting the sales of e-cigarettes to youth.”
			“Companies should not be able to claim that e-cigarettes are a cessation aid unless they are approved by the FDA for that purpose.”	

Table 5.3. (B. Continued)

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
American Lung Association (2014, 2015)	“Until and unless the FDA approves a specific e-cigarette for use as a tobacco cessation aid, the American Lung Association does not support any direct or implied claims that e-cigarettes help smokers quit.”	“There is currently no scientific evidence establishing the safety of e-cigarettes.” “FDA found detectable levels of toxic cancer-causing chemicals, including an ingredient used in anti-freeze, in two leading brands of e-cigarettes and 18 various cartridges.” “The lab tests also found that cartridges labeled as nicotine-free had traceable levels of nicotine.” “Nicotine is believed to contribute to increased incidence of premature birth, and low birth weight.” “Research has also shown a negative impact on pulmonary function in newborns.”	“The FDA has not approved any e-cigarettes as a safe or effective method to help smokers quit.”	“Including e-cigarettes in smokefree laws and ordinances.” “State laws that would prohibit the sale of any flavored e-cigarette product.” “Taxing e-cigarettes at a rate equivalent with all tobacco products, including cigarettes.” “Eliminating e-cigarette sales to youth, otherwise restricting youth access to e-cigarettes and requiring e-cigarette retailers to be licensed.” “E-cigarettes should be defined as tobacco products.” “Opposes creating new definitions for ‘vapor products’ and/or ‘alternative nicotine products’ in state laws.”
Americans for Nonsmokers’ Rights (ANR) (n.d.a; n.d.b)	“ESDs are not proven cessation devices.” “Many people become ‘stable dual-users’ who use both cigarettes and ESDs.”	“Americans for Nonsmokers’ Rights recommends that e-cigarettes not be used in areas where people will be exposed to the vapors they emit.” “Electronic smoking device aerosol is not water vapor...” - The aerosol (incorrectly called vapor) contains nicotine, hazardous ultrafine particles that lodge deeply in the lungs and toxins known to cause cancer.”	“Electronic smoking devices are currently unregulated products.” “[ANR] . . . encourages municipalities and states to prohibit the use of ESDs in all smokefree venues.”	“Electronic cigarettes are not a safe alternative!”

Table 5.3. (Continued)
C. World Health Organization

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
World Health Organization (WHO) (Bates 2014; WHO 2014b)	“Prohibit manufacturers and third parties from making health claims for ENDS, including that ENDS are smoking cessation aids.” “The regulatory standard for cessation claims and approval as cessation aids should remain an appropriate body of evidence, based on well-controlled clinical trials.”	“ENDS users should be legally requested not to use ENDS indoors, especially where smoking is banned until exhaled vapour is proven to be not harmful to bystanders and reasonable evidence exists that smoke-free policy enforcement is not undermined. If smoke-free legislation is not fully developed according to Article 8 of the WHO FCTC and the guidelines for its implementation, this should be done as soon as possible.” “Health warnings should be commensurate with proven health risks.”	“Parties should contemplate putting in place an effective restriction on ENDS advertising, promotion and sponsorship.” “Protection from vested commercial interests.” “Governments are recommended to use or strengthen their existing tobacco surveillance and monitoring systems to assess developments in ENDS and nicotine use by sex and age.”	“Overall, in its public communication WHO portrays e-cigarettes as a threat to public health.” “Encourage smoking cessation and provide a quitline number if one exists.”
World Health Organization (WHO) (Bates 2014; WHO 2014b)	“For ENDS products to be approved for smoking cessation by the suitable regulatory agency, the appropriate balance should be reached between providing accurate scientific information to the public about the risk of ENDS use and its potential benefits as compared with smoking.”	—	—	—
European Union (EU) (European Parliament and Council 2014; WHO Framework Convention on Tobacco Control 2014)	—	“Certain additives used to create the impression that tobacco products have health benefits, as well as those with [carcinogenic, mutagenic, or reprotoxic] properties in unburnt form, should be prohibited in order to ensure uniform rules throughout the Union and a high level of protection of human health.”	“The prohibition of tobacco products with characterizing flavours does not preclude the use of individual additives outright, but it does oblige manufacturers to reduce the additive or the combination of additives.” “Electronic cigarettes and refill containers should be regulated by this Directive.”	- New directive: May 2014. - New rules applied: First half of 2016. “Aims at ensuring equal treatment across the EU for nicotine-containing e-cigarettes (products that do not contain nicotine are not covered by the Directive).”

Table 5.3. (C. Continued)

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
(Continued)	—	“Electronic cigarettes and refill containers could create a health risk when in the hands of children—it is necessary to ensure products are child and tamperproof.” “Nicotine-containing liquid should only be placed on the market in electronic cigarettes or in refill containers that meet certain safety and quality requirements.”	“Where the manufacturer of the relevant product is not established in the Union, the importer of that product should bear the responsibilities relating to the compliance of those products with this Directive.” “Nicotine-containing liquid should only be allowed to be placed on the market, where the nicotine concentration does not exceed 20 mg/ml.” “Only electronic cigarettes that deliver nicotine doses at consistent levels should be allowed to be placed on the market.” “The labeling and packaging of [e-cigarettes] should display sufficient and appropriate information on their safe use.”	“Electronic cigarettes can develop into a gateway to nicotine addiction and ultimately traditional tobacco consumption, as they mimic and normalize the action of smoking. - For this reason, it is appropriate to adopt a restrictive approach to advertising electronic cigarettes and refill containers.”
CAP/BCAP (UK) (2014)	—	“Ads cannot convey health benefits or claim that they are safer or healthier than smoking tobacco.”	“Ads must not be likely to appeal particularly to people under 18, especially by reflecting or being associated with youth culture.” “People shown using e-cigarettes or playing a significant role must neither be, nor seem to be, under 25.” “Ads must not be directed at people under 18 through the selection of media or the context in which they appear.” “Ads must not encourage nonsmokers or nonnicotine users to use e-cigarettes.” “Ads must make clear that the product is an e-cigarette and not a tobacco product.” “Ads on TV and radio will be subject to scheduling restrictions to reduce the chance of e-cigarette advertisements being seen or heard by children.”	- Effective date: November 10, 2014. “The rules place an emphasis on the protection of young people and ads must avoid containing anything that promotes the use of a tobacco product or that shows the use of a tobacco product in a positive light.” - CAP: Write and maintain the UK advertising codes.
Public Health England (UK) (Britton and Bogdanovica 2014; CAMQUIT n.d.)	—	—	“Under the terms of the new Tobacco Product Directive (TPD) . . . advertising of nicotine-containing devices that are not licensed as medicines will be prohibited, products will be required to carry health warnings, meet purity and emission standards that are yet to be defined.”	- Effective date: 2016. “The UK [Medicines and Healthcare products Regulatory Agency] announced that from 2016, it intended to regulate electronic cigarettes and other nicotine-containing products as medicines by function, and

Organization	Organizational position on cessation	Organizational position on harm	Organizational position on regulation	General comments
(Continued)			“Under the terms of the new Tobacco Product Directive (TPD) . . . advertising of nicotine-containing devices that are not licensed as medicines will be prohibited, products will be required to carry health warnings, meet purity and emission standards that are yet to be defined.”	thus require manufacture to medicinal purity and delivery standards, and proactive controls on advertising.”
International Union Against Tuberculosis and Lung Cancer (2013)	“The benefits of e-cigarettes have not been scientifically proven.” “Very few studies have assessed ECs/ ENDS as a harm reduction and cessation aid and with conflicting findings.”	“The safety of ECs or ENDS has not been scientifically demonstrated.”^{xxx} “Adverse health effects for [secondhand smoke] cannot be excluded because the use of electronic cigarettes leads to emission of fine and ultrafine inhalable liquid particles, nicotine and cancer-causing substances into indoor air.”	“A range of current and proposed legislative and regulatory options exists.” “Brazil, Norway, and Singapore have banned ECs/ENDS completely.” “ENDS could undermine the implementation of WHO FCTC Article 12 (de-normalisation of tobacco use).” “Use of ENDS could also hamper the implementation of Article 8 (protection from exposure to tobacco smoke).”	“The Union strongly supports the regulation of the manufacture, marketing and sale of Electronic cigarettes (ECs) or electronic nicotine delivery systems (ENDS); - the preferred option is to regulate ECs or ENDS as medicines.” “The Union is concerned that the marketing, awareness and use of ECs or ENDS is growing rapidly.”

Note: AARC = American Association for Respiratory Care; ACP = American College of Physicians; ACS = American Cancer Society; AHA = American Heart Association; ANR = Americans for Nonsmokers’ Rights; CAP/BCAP = Committees of Advertising Practice/Broadcast Committee of Advertising Practice; CDC = Centers for Disease Control and Prevention; CTP = Center for Tobacco Products; ECs = electronic cigarettes; ENDS = electronic nicotine delivery systems; ERS = European Respiratory Society; ESDs = electronic smoking devices; EU = European Union; FCTC = Framework Convention for Tobacco Control; FDA = U.S. Food and Drug Administration; UK = United Kingdom; WHO = World Health Organization.

e-cigarettes for the cessation of smoking is not supported by the bulk of the available scientific evidence (Hartmann-Boyce et al. 2016). Both the American Association of Cancer Research and the American Society of Clinical Oncology recommend against advising the use of e-cigarettes for cessation (Brandon et al. 2015b). The U.S. Preventive Services Task Force found that there is insufficient evidence that e-cigarettes are an effective smoking cessation tool in adults, including pregnant women (Agency for Healthcare Research and Quality 2015).

The clinical care setting is a critical venue for taking evidence-based approaches for enhancing smoking cessation and increasing the protection of susceptible groups against exposure to secondhand smoke (USDHHS 2014). However, research on e-cigarettes in relation to this set of venues is lacking and urgently needed. Regardless, some pragmatic approaches have been proposed. For example, the American Academy of Pediatrics (AAP) gives advice on how pediatricians can approach questioning about the use of e-cigarettes. As of October 2015, the AAP's position on e-cigarettes is that sales to minors should be prohibited; flavors that appeal to youth should be prohibited; and measures against the use of e-cigarette products need to be included in requirements for maintaining smoke-free environments, such as in restaurants and workplaces (AAP 2015a).

Case Studies

Case studies in California and North Dakota demonstrate how e-cigarette policies have been enacted at the local and state levels, and they provide potential models of how cities, counties, and other states might address e-cigarettes in their jurisdictions.

City of Hayward Takes Bold Steps to Address Tobacco Products Aimed at Kids

In response to the “D” grade that the city of Hayward received in 2011 from the American Lung Association in California for its efforts to protect youth from tobacco sales, the city council directed its staff to develop regulations to address the problem of youth tobacco sales. Draft regulations were presented at a city planning meeting in 2012, followed by a series of community meetings and hearings that culminated in the Hayward city council's adoption of a 45-day moratorium to begin in January 2014 on the issuance of business licenses or building permits for any new tobacco retailers. The following month, the moratorium was extended another 15 months to provide more time to research and consider the issue (City of Hayward 2014).

On July 1, 2014, the Hayward city council unanimously adopted an ordinance that requires sellers of tobacco products and “electronic smoking devices” to obtain annually a \$400 tobacco retailer license that covers the cost of an annual inspection for compliance with federal, state, local, tribal, and territorial tobacco control laws. The ordinance allowed the city's existing 142 tobacco retailers, 8 e-cigarette retailers, and 2 hookah lounges to continue operating at their current locations; however, new sellers must obtain a conditional use permit, are restricted to special commercial zones, and may not locate within 500 feet of residential areas or child-sensitive areas (e.g., schools and parks) or within 500 feet of an existing tobacco seller. It also prohibits new hookah lounges or vaping lounges from opening within the city.

The ordinance also contains provisions to prohibit self-service displays of tobacco products and e-cigarettes and to regulate the sales of cigars, flavored products, and imitation tobacco products. Cigars selling for less than \$5 each are required to be sold in pack sizes of five or more, and the sale of flavored traditional tobacco products, e-cigarettes, and imitation tobacco products (e.g., candy cigarettes, bubble gum chew) is prohibited within 500 feet of schools for any business not selling these products before July 1, 2014.

Penalties range from \$1,500 for a first violation and possible suspension to a complete revocation of a license after three violations within a 3-year period (City of Hayward 2014; n.d.a.). Active enforcement of the ordinance began in April 2015 (City of Hayward n.d.b.).

Throughout the process, Hayward officials and staff relied heavily on materials from the American Lung Association, the Center for Tobacco Policy and Organizing, and ChangeLab Solutions to provide the public health and legal rationale for supporting the provisions. Hayward's tobacco retail licensing effort was also supported by the tobacco control program of the Alameda County public health department, which used monies from its Master Settlement Agreement to fund the Hayward police department to conduct youth decoy operations and local community and youth organizations to conduct educational outreach (City of Hayward 2014). Collectively, these resources informed the Hayward city council's decision-making process.

North Dakota's Statewide Clean Indoor Air Law Prohibits Conventional Tobacco Products and E-Cigarettes

In November 2012, North Dakota achieved a remarkable victory for statewide clean indoor air (BreatheND n.d.a.) despite major obstacles, including a harsh winter climate, an adult smoking rate of 21.9% (CDC 2013), and several prior failed legislative attempts to close exemptions in the state's 2005 clean indoor air law (CDC 2014). Despite these impediments, two-thirds of the state voted to prohibit both the smoking of conventional tobacco products and use of e-cigarettes in all non-hospitality workplaces; restaurants; bars; hotel guest rooms and communal areas; health care facilities; assisted living facilities; all licensed child and adult day care facilities; gaming facilities; indoor areas of sports arenas; and within 20 feet of entrances, exits, operable windows, air intakes, and ventilation systems of enclosed areas where smoking is not allowed (BreatheND n.d.b.). Additionally, the law provided no exemptions for tobacco-only retail or "vape shops" (Americans for Nonsmokers' Rights Foundation 2015, n.d.).

The 2012 ballot initiative on statewide clean indoor air resulted from the lack of progress in working with the legislature to try to close smoking exemptions in the state law. The initiative's sponsors, Tobacco Free North Dakota and the American Lung Association in North Dakota, worked closely with the Tobacco Control Legal Consortium to draft policy language, which included prohibiting the use of e-cigarettes anywhere smoking was prohibited. The sponsors approached stakeholders and assessed public support. Little opposition was encountered to prohibiting the use of e-cigarettes indoors. In addition to the sponsors' efforts, the North Dakota Center for Tobacco Prevention and Control Policy conducted a media campaign and worked with local partners to educate their communities, resulting in 11 smokefree ordinances prior to the issuing of the statewide ballot initiative. The landslide victory (66% vs. 33%) in favor of clean indoor air, with the initiative successfully carried in every one of North Dakota's 53 counties, demonstrated widespread public support for clean indoor air (Ballotpedia 2012).

Only a few years later, the law continues to enjoy strong public support from nonsmokers (84.4%) and smokers (58%) alike. Compliance with the law is comparable to cigarette smoking; just 16.8% of North Dakotans reported having observed smoking indoors in areas where it was prohibited, and 23.2% reported having seen e-cigarettes used indoors in such places. Local enforcement personnel confirm a high level of compliance, reporting violations primarily related to smoking within 20 feet of entrances. To date, the only prosecuted violation of the law involved the sampling of an e-cigarette product inside a "vape shop" (BreatheND 2014). In hindsight, the decision to include e-cigarettes in North Dakota's smokefree law was helpful, given increasing concerns about involuntary exposure to nicotine and other aerosolized e-cigarette emissions.

Summary and Recommendations

The Surgeon General has long played a leading role in identifying the harms of tobacco use and documenting the most effective ways to reduce them. This report comes amid the

rising use of e-cigarettes among the nation's youth and young adults. It calls attention to this problem and the need to implement immediately a comprehensive strategy to minimize any negative public health impact now and in the future, giving consideration to the potential for youth to be harmed from e-cigarettes while, simultaneously, acknowledging that gains might be made if the use of combustible tobacco products fell among adult smokers. Chapters 1–4 documented the particular challenges posed by the rapid emergence and dynamic nature of e-cigarette use among youth and young adults. The marketplace is diverse, and although it includes the large tobacco companies, e-cigarettes are sold in thousands of “vape shops” and other small commercial locations and on the Internet. Marketing strategies exploit social media, reaching widely and with tailored targeting to consumers.

The differences notwithstanding, the principles and strategies articulated in the 2014 Surgeon General's report and prior reports remain relevant to e-cigarettes. The 2014 report was written not long after the use of e-cigarettes began to surge dramatically; that report commented on the need for rapid elimination of conventional cigarettes and other combustible tobacco products but did not specify a role for e-cigarettes or discuss strategies to minimize adverse effects among youth and young adults (USDHHS 2014). The report's final chapter, however, set out an evidence-based strategy for the future. The present report builds on this foundation, adding recommendations related to e-cigarettes.

Conclusion

- 1) The dynamic nature of the e-cigarette landscape calls for expansion and enhancement of tobacco-related surveillance to include (a) tracking patterns of use in priority populations; (b) monitoring the characteristics of the retail market; (c) examining policies at the national, state, local, tribal, and territorial levels; (d) examining the channels and messaging for marketing e-cigarettes in order to more fully understand the impact future regulations could have; and (e) searching for sentinel health events in youth and young adult e-cigarette users, while longer-term health consequences are tracked.
- 2) Strategic, comprehensive research is critical to identify and characterize the potential health risks from e-cigarette use, particularly among youth and young adults.
- 3) The adoption of public health strategies that are pre-cautionary to protect youth and young adults from adverse effects related to e-cigarettes is justified.
- 4) A broad program of behavioral, communications, and educational research is crucial to assess how youth perceive e-cigarettes and associated marketing messages, and to determine what kinds of tobacco control communication strategies and channels are most effective.
- 5) Health professionals represent an important channel for education about e-cigarettes, particularly for youth and young adults.
- 6) Diverse actions, modeled after evidence-based tobacco control strategies, can be taken at the state, local, tribal, and territorial levels to address e-cigarette use among youth and young adults, including incorporating e-cigarettes into smoke-free policies; preventing the access of youth to e-cigarettes; price and tax policies; retail licensure; regulation of e-cigarette marketing that is likely to attract youth and young

adults, to the extent feasible under the law; and educational initiatives targeting youth and young adults. Among others, research focused on policy, economics, and the e-cigarette industry will aid in the development and implementation of evidence-based strategies and best practices.

THE CALL TO ACTION

The Call to Action on E-Cigarette Use among Youth and Young Adults

The Surgeon General issues this Call to Action on e-cigarettes, specifically focusing on youth and young adults, to accelerate policies and programs that can reduce e-cigarette use among young people. This Call to Action comes amid the dramatic increase in e-cigarette use among our nation's youth and young adults. It highlights the need to implement proven strategies that will prevent potentially harmful effects of e-cigarette use among young people. The previous chapters explained what we know and do not know about e-cigarettes and reviewed policy options. Gaps in scientific evidence still exist, and this Call to Action is being issued while these products and their patterns of use are changing quickly. However,

policies and strategies are available that can clearly reduce the public health threat posed by e-cigarette use among young people.

Use of e-cigarettes is increasing rapidly among young people, even among those who have never smoked cigarettes.

This Call to Action presents six goals and related strategies that should guide efforts to reduce e-cigarette use among youth and young adults. To achieve these goals, we must work together, which means working with individuals and families; civic and community leaders; public health and health care professionals; e-cigarette manufacturers and retailers; voluntary health agencies; researchers; and other stakeholders.

Stakeholders Who Can Take Action

- Individuals, parents, and families
- Teachers, coaches, and other youth influencers
- Civic and community leaders
- Public health and health care professionals
- Researchers
- Federal government
- State, local, tribal, and territorial governments
- E-cigarette manufacturers, distributors, and retailers
- Voluntary health agencies, non-governmental organizations, and other community- and faith-based organizations

Goal 1. First, Do No Harm

Since 1964, reports from the U.S. Surgeon General have led the way in identifying the harms of tobacco use and detailing the most effective ways to reduce the dangerous effects of tobacco use. For example, reports from 1994 and 2012 outlined proven strategies to prevent and reduce tobacco use among youth and young adults (U.S. Department of Health and Human Services [USDHHS] 1994, 2012). Building on these and other past reports, this Call to Action considers the harms of e-cigarette use among youth and young adults and stresses the importance of strategies that will protect young people from the adverse consequences of these new products.

Strategy 1A.

Implement a comprehensive strategy to address e-cigarettes that will avoid adverse consequences and give careful consideration to the risks for youth and young adults. This can be done by including e-cigarettes in policies and programs related to conventional cigarette smoking at the national, state, local, tribal, and territorial levels.

We have many effective strategies to prevent tobacco use among youth and young adults (USDHHS 2012), and many of these strategies can also be applied to e-cigarettes. A strategy to address e-cigarette use among young people should be precautionary. A precautionary approach urges action to prevent harm when there is scientific uncertainty. That is, when there is inadequate or early knowledge, public health decisions should be made on the basis of precaution to prevent harm, rather than on certain risk. This approach requires proof that a product *is not* harmful—especially for youth—rather than proof that it *is* harmful. The burden of proof regarding product safety should be placed on those who wish to market and sell such tobacco products, rather than the public health community charged with protecting the public's health. The harms of nicotine exposure in youth and young adults are well-documented in this report and warrant this Call to Action (see Chapter 3). We must protect the health of our nation's young people by assuring that there will be no harm to youth from e-cigarettes. The stakeholders identified on the previous page should work together to prevent and reduce the use of all forms of tobacco products, including e-cigarettes, among our nation's youth and young adults. A comprehensive strategy includes:

- Implementing the U.S. Food and Drug Administration's (FDA's) authority to regulate tobacco products in order to provide oversight of the manufacturing, distribution, and marketing of e-cigarettes, particularly as they relate to youth and young adults;
- Funding comprehensive statewide tobacco control programs at levels recommended by the Centers for Disease Control and Prevention (CDC);
- Implementing comprehensive clean indoor air policies that protect people from exposure to secondhand tobacco smoke and the aerosol emitted from e-cigarettes;
- Raising and strongly enforcing minimum age-of-sale laws for all tobacco products, including e-cigarettes, to prevent initiation at young ages;

Use of e-cigarettes can expose young people to nicotine. Nicotine can be highly addictive and can harm brain development. Nicotine use may also lead to the use of other tobacco or nicotine-containing products.

- Setting price policies for e-cigarettes, which could include taxation policies;
- Restricting advertising and marketing that encourages youth and young adults to use e-cigarettes;
- Sponsoring high-impact media campaigns to educate the public using evidence-based information about the consequences of e-cigarette use among youth and young adults, including the harms of nicotine on the developing brain; and
- Expanding tobacco control and prevention research efforts to increase our understanding of the evolving landscape of e-cigarettes.

These components make up an evidence-based strategy. However, the e-cigarette marketplace is diverse and continues to evolve. Thus, ongoing efforts should rapidly and effectively track and adapt to such changes, thereby protecting our nation's young people from the consequences of e-cigarette use and exposure to secondhand aerosol.

Strategy 1B.

Provide consistent and evidence-based messages about the health risks of e-cigarette use and exposure to secondhand aerosol from e-cigarettes.

Research on e-cigarettes is ongoing, and the e-cigarette marketplace continues to evolve. Even so, a sufficient body of evidence justifies actions taken now to prevent and reduce the use of e-cigarettes and exposure to secondhand aerosol from e-cigarettes, particularly among youth and young adults. Most important, many health risks are already known, and sufficient information exists to take action to minimize potential harms. The evidence is most compelling for nicotine. As part of comprehensive reviews, previous Surgeon General's reports have provided causal findings on the development of addiction and other health consequences of exposure to nicotine (USDHHS 1988, 2014). Beyond addiction, intake of nicotine by young people can harm brain development (Chapter 3).

Additionally, aerosol from e-cigarettes contains toxins that can harm the body, and the flavorings used in these products cannot be considered safe for inhalation, either firsthand or secondhand (Chapter 3). For example, some flavorings have been known to be associated with pulmonary toxicity (Allen et al. 2016).

Messaging about the potential role of e-cigarettes in reducing the burden of tobacco-related diseases should note that e-cigarette products that deliver nicotine are not considered safe, particularly for youth and young adults, even before researchers fully characterize and quantify all of their health risks, including possible permanent changes to the adolescent brain and lungs.

The use of any tobacco product, including e-cigarettes, among young people is unsafe.

Goal 2. Provide Information about the Dangers of E-Cigarette Use among Youth and Young Adults

Once youth and young adults start using products that contain nicotine, including e-cigarettes, they can become addicted. Such addiction has the potential to lead to long-term use of products that contain nicotine, such as cigarettes. Most adolescents who use tobacco already use more than one nicotine-containing product and are not just using e-cigarettes alone (Chapter 2). The majority of tobacco users start before they are 18 years of age, and almost no one starts after age 25 (USDHHS 2012). Therefore, the best way to protect young people from the harms of tobacco use, including e-cigarettes, is to prevent the use of these products altogether. Prevention should start with robust public policies that make it easy for youth not to use tobacco and harder for them to use any tobacco products. Parents, teachers, health professionals, and other influencers of youth should be educated about the risks of e-cigarette use. They can then help educate their own children as well as other young people about the harms of e-cigarettes and the risk of a potential lifetime of nicotine addiction.

Use of e-cigarettes and exposure to nicotine is particularly dangerous for pregnant women. Nicotine is toxic to the fetus and impairs fetal brain and lung development.

Strategy 2A.

Educate parents, teachers, coaches, and other influencers of youth about the risks of e-cigarette use among youth and young adults.

Parents, guardians, teachers, coaches, health professionals, faith leaders, and other persons whose advice and behavior influence youth play critical roles in protecting youth and young adults from the harms of e-cigarette use and exposure to the secondhand aerosol emitted from these devices. Most adults are familiar with some of the dangers of using tobacco products, especially conventional cigarettes, and of exposure to secondhand tobacco smoke. Because of these dangers, many adults have taken steps to keep children safe. However, most adults are not aware of the potential risks of using e-cigarettes and exposure to secondhand aerosol, and e-cigarette marketing often promotes these products as safe alternatives to smoking conventional cigarettes. But messaging about the dangers is essential. For example, the use of these products can lead to nicotine addiction, harm brain development, and lead to continued tobacco use.

Parents, teachers, coaches, and others can protect their children and other young people by educating them about e-cigarettes:

- Talk openly about the harms of nicotine and tobacco use.
- Express firmly the idea that young people should not use any tobacco products, including e-cigarettes.
- Do not let any individuals use e-cigarettes or other tobacco products around children.
- Ask health care providers, adults, and parents to discuss with children the health risks of using e-cigarettes, such as nicotine addiction.
- Patronize restaurants and other places that do not allow the use of e-cigarettes indoors, and let business owners that allow e-cigarette use indoors know that it is not as safe as clean air or even legal in many places.
- Make sure children's day care centers, schools, and universities are completely tobacco-free, including being free of e-cigarettes. A comprehensive tobacco-free campus policy prohibits any tobacco use, including e-cigarettes, on school property by anyone at any time. These policies should be expanded to include school events that are held off campus.
- Prohibit tobacco and e-cigarette company sponsorship of teams or events, promotional activities, and offers of educational materials for preventing tobacco use among youth.
- Make homes and cars completely tobacco-free, including the use of e-cigarettes. This means no use by family members, friends, or guests. Opening a window does not fully protect against exposure to secondhand cigarette smoke or from the secondhand aerosol from e-cigarettes. For youth and young adults to be fully protected from indoor exposure, all indoor environments must be 100% free from tobacco smoke and e-cigarette aerosol.
- Set an example by being tobacco-free.
- Provide positive support and encouragement to anyone who is trying to quit tobacco.

E-cigarettes are now the most common form of tobacco used by young people. High school students use e-cigarettes more than adults.

Research suggests that youth and young adults are not as aware of the health consequences of e-cigarette use as they are with the consequences of cigarette smoking (Chapter 2) (Pearson et al. 2012; Richardson et al. 2014; Tan and Bigman 2014). FDA has the authority to require health warnings on tobacco products and tobacco advertising. In addition, FDA and other federal entities, along with state and local organizations, can carry out educational campaigns to better inform the public, especially parents, and increase their understanding of the harms of e-cigarette use.

Strategy 2B.

Educate health professionals about the risks of e-cigarette use among youth and young adults.

The health care setting is an ideal place to educate people of all ages on the potential risks of e-cigarette use and exposure to secondhand aerosol from e-cigarettes. Because e-cigarettes are a relatively new product, health care professionals frequently face a lot of questions about them. These often include questions related to the risks of using e-cigarettes and whether these products can help people to quit smoking. No e-cigarettes have been approved as safe and effective cessation aids.

For youth, in particular, sufficient evidence shows that the use of nicotine is not safe regardless of the delivery device: combustible, non-combustible, or electronic (USDHHS 2014; see also Chapter 3). Thus, health care professionals should warn youth and youth influencers, such as parents, about the health risks of using any product that contains nicotine, including e-cigarettes. They should also warn youth about the dangers of using other substances, such as marijuana, in e-cigarette devices (American Academy of Pediatrics 2015).

Goal 3. Continue to Regulate E-Cigarettes at the Federal Level to Protect Public Health

In 2009, the *Family Smoking Prevention and Tobacco Control Act* (Tobacco Control Act) provided FDA with authority to regulate tobacco products in a manner that is “appropriate for the protection of public health” (e.g., §§ 906(d)(1), 907(a)(3)(A) & (a)(4)(A), and § 910(c)(2)(A) of the *Federal Food, Drug, and Cosmetic Act*, as amended by the Tobacco Control Act) (*Family Smoking Prevention and Tobacco Control Act* 2009, p. 1786). The Tobacco Control Act also requires FDA to consider in regulatory actions the health effects at the individual and population levels, including the impacts on the initiation of measures taken to quit tobacco use as well as effects on relapse among former tobacco users. But FDA is not the only federal agency that can address certain aspects of e-cigarettes (see Chapter 5, Table 5.2).

**Strategy 3A.**

Implement FDA regulatory authority over the manufacturing, marketing, and distribution of e-cigarettes.

A federal appellate court decision titled *Sottera, Inc. v. Food & Drug Administration* (2010) determined that FDA can regulate e-cigarettes and other products made or derived from tobacco under the Tobacco Control Act, and that these products are not drugs or devices under the *Food, Drug, and Cosmetic Act* unless marketed as therapeutic or smoking cessation products. In May 2016, FDA finalized a rule deeming most products meeting the definition of a tobacco product, including e-cigarettes, subject to regulation under the Tobacco Control Act. The regulation went into effect on August 8, 2016 (but is under litigation) (FDA 2016).

FDA's rule for e-cigarettes includes several provisions that can help protect youth and young adults from the harms of e-cigarettes, such as the following:

- Prohibiting the sale of e-cigarettes to youth who are under 18 years of age (both in person and online);
- Requiring proof of age at the point of purchase;
- Prohibiting vending machine sales in all facilities where children are allowed to enter;
- Prohibiting the distribution of free samples;
- Requiring health warnings about nicotine on packaging and in advertisements;
- Requiring manufacturers to register their e-cigarette products with FDA and disclose the ingredients and levels of harmful and potentially harmful constituents in those products to that agency;
- Requiring premarket review of new or changed tobacco products and authorization by FDA before they can be introduced into the marketplace; and
- Requiring manufacturers that intend to market e-cigarettes for use to reduce harm or risk of tobacco-related disease to receive authorization from FDA based on scientific evidence that the product is less harmful or presents less risk to the public.

This authority allows FDA to undertake future regulatory actions, if determined appropriate for the protection of public health, including:

- Within constitutional limitations, restricting promotion, marketing, and advertising of e-cigarettes;
- Restricting Internet sales and requiring age verification on websites and upon delivery;
- Prohibiting characterizing flavors;
- Promulgating product standards to reduce the toxicity, addictiveness, or appeal of tobacco products;
- Regulating packaging, including requiring minimum package sizes, mandating child-resistant packaging, and requiring health warnings; and
- Prohibiting self-service displays.

Despite gaining this broad authority, FDA does not have specific authority for certain regulatory actions. For example, FDA generally does not restrict tobacco use in public places, levy taxes on tobacco products, or restrict sales to only certain types of retailers (e.g., pharmacies); and FDA cannot completely eliminate nicotine in tobacco products, require prescriptions for tobacco products, or raise the minimum age for sale of tobacco products above 18.

Other complementary comprehensive tobacco control strategies at the state, local, tribal, and territorial levels include:

- Implementing comprehensive clean indoor air laws;
- Prohibiting sales to those under 21 years of age;
- Increasing prices of tobacco products; and
- Developing high-impact countermarketing campaigns.

Effective action at the state and local levels is critical to fully protecting young people from the harms of e-cigarettes.

Strategy 3B.

Reinforce other federal agencies as they implement programs and policies to address e-cigarettes.

Of the other federal agencies that play a role in implementing strategies to address e-cigarettes (see Chapter 5, Table 5.2), some target specific populations (e.g., the Department of Defense and the U.S. Department of Veterans Affairs); others cover specific areas (e.g., the General Services Administration, National Park Service); and some focus on certain aspects of e-cigarettes (e.g., the Federal Trade Commission, the U.S. Department of Transportation, and the U.S. Environmental Protection Agency). Specific strategies to address e-cigarettes could include those that protect employees, customers, and visitors from exposure to secondhand aerosol, support and encourage tobacco cessation, and curb youth-targeted or false advertising. For example, the National Park Service (2015) implemented a policy to protect employees and visitors from exposure to secondhand aerosol from e-cigarettes.

Goal 4. Programs and Policies to Prevent E-Cigarette Use among Youth and Young Adults

Subject to certain exceptions, the Tobacco Control Act does not limit the authority of state, local, tribal, and territorial governments to enact any tobacco-related policies related to the sale, distribution, or possession of tobacco products; exposure to these products; or access to them. This broad preservation of authority enables states and localities to adopt many comprehensive tobacco control strategies that have been proven to prevent and reduce tobacco use among youth and young adults. That means that state, local, tribal, and territorial governments could act first in developing regulations, policies, and programs that minimize any individual- and population-level harms of e-cigarettes. The strongest, most innovative tobacco control policies typically have originated at the local level before eventually being adopted at the state level. However, it is important that these strategies are developed with evaluators and epidemiologists that can collect robust data to inform the implementation and sustainment of such strategies.

Strategy 4A.

State, local, tribal, and territorial governments should implement population-level strategies to reduce e-cigarette use among youth and young adults, such as including e-cigarettes in smokefree indoor air policies, restricting youth access to e-cigarettes in retail settings, licensing retailers, and establishing specific package requirements.

Over 50 years of research offers a strong body of evidence on the effectiveness of certain tobacco prevention and control measures. Much of this evidence can also be applied to e-cigarettes. And from this evidence, state, local, tribal, and territorial entities can take a variety of actions to address e-cigarettes, such as:

- Including e-cigarettes in smokefree indoor air policies;
- Restricting youth access to e-cigarettes in retail settings;
- Licensing retailers; and
- Establishing specific package requirements.

Including E-Cigarettes in Smokefree Indoor Air Policies

Most smokefree indoor air policies were put in place before the great rise in e-cigarette use. Because of that, these policies may not cover e-cigarettes or exposure to the aerosol they produce. Aerosol from e-cigarettes is not harmless (CDC 2014). Smokefree indoor air policies should be updated to prohibit the use of both conventional cigarettes and e-cigarettes, thereby preserving standards for clean indoor air. Efforts to include e-cigarettes in smokefree laws should also uphold or strengthen, not weaken, existing protections against exposure to secondhand smoke.

Including e-cigarettes in smokefree indoor air policies can:

- Eliminate health risks from exposure to secondhand aerosol from e-cigarettes;
- Discourage people from using both combustible and electronic tobacco products (dual use);
- Simplify compliance with and enforcement of existing smokefree laws;
- Help to reduce the use of e-cigarettes among youth and young adults; and
- Maintain tobacco-free norms.

Aerosol from e-cigarettes is not harmless.
--

To date, several states and several hundred communities include e-cigarettes in comprehensive smoke-free laws that prohibit smoking in all indoor areas of public places,

including worksites, restaurants, bars, and gambling facilities (Americans for Nonsmokers' Rights Foundation 2015; CDC n.d.).

Restricting Youth Access to E-Cigarettes

When laws prohibiting tobacco sales to youth are strong and actively enforced with the education of retailers, they successfully reduce tobacco use among youth (Task Force on Community Preventive Services 2001; Zaza et al. 2005). To date, all 50 states and the District of Columbia restrict the sale of tobacco products to minors (CDC n.d.). Extending such laws to include e-cigarettes can further protect youth from exposure to nicotine, which nearly all states have done. Specific strategies can be implemented to deter the access of youth to e-cigarettes and their use in this population:

- Restricting the sale of e-cigarettes to minors;
- Placing restrictions on Internet sales of all tobacco products and e-cigarettes, including requirements for verifying age and providing identification at the time of purchase and upon delivery;
- Requiring age verification at the point of purchase;
- Displaying clear signage in retail locations about required age for sale;
- Prohibiting the sale of e-cigarettes from vending machines;
- Eliminating self-service displays of e-cigarettes; and
- Enforcing laws on the retail sale of e-cigarettes to minors.

Nearly all states prohibit the sale of e-cigarettes to youth under 18 years of age. Some states have a higher minimum age for purchase (e.g., 19 or 21 years of age) (CDC 2014). Some e-cigarette manufacturers have supported state legislation to prevent minors from purchasing e-cigarettes (Healy 2014). Their actions may, to some extent, be responsible for why these age-of-sale laws have been adopted more quickly than laws that prohibit e-cigarette use in public indoor spaces. However, industry-supported, youth-access bills have contained provisions that undermine prevention efforts for youth, including preemption of stricter local policies and weak requirements for enforcement (USDHHS 2012). Additionally, laws prohibiting sales to minors are likely to have limited effectiveness as a prevention

strategy if they are not aggressively enforced and are not coupled with proven interventions, such as comprehensive smoke-free laws, pricing strategies, or public health campaigns (USDHHS 2012, 2014). Ensuring that e-cigarettes are regulated at the state and local levels can facilitate the application of additional tobacco control policies regarding e-cigarettes.

Many actions can help to protect young people from the harms of e-cigarettes, such as including e-cigarettes in smokefree indoor air policies, restricting youth access to e-cigarettes *in retail settings*, *licensing retailers*, and *setting specific package requirements*.

Licensing Retailers

Licensing is another strategy to control access to e-cigarettes among youth and young adults. A tobacco-related license can authorize a business to manufacture, distribute, or sell tobacco products (McLaughlin 2010). Licensing requirements help to prevent sales to minors, prevent evasion of tobacco excise taxes, ensure that licensees comply with tobacco-related laws, and promote safe manufacturing practices (ChangeLab Solutions 2012). Businesses that repeatedly violate these laws can have their right to engage in commercial activity suspended or their licenses permanently removed. The possibility of these outcomes provides a strong incentive to comply with license requirements. Licensing may also be used to restrict the sale of flavored products or to address consumer and worker safety issues involved with the mixing of liquids for e-cigarette products (e-liquids).

Establishing Specific Packaging Requirements

Federal, state, local, tribal, and territorial governments are actively considering the potential harms of e-liquids. Exposure to these liquids may lead to nicotine and other types of poisoning. Calls to poison control centers about e-cigarettes and e-liquids have been on the rise, and about half of these calls are for incidents involving young children (American Association of Poison Control Centers 2015). The most common adverse health effects of poisoning are vomiting, nausea, and eye irritation, but some deaths have occurred as well. Developing strategies to monitor and prevent future poisonings is critical.

Calls to poison control centers about e-cigarettes are on the rise. A large portion of these calls are for incidents involving young children.

Enacting laws that require e-liquids to be labeled and sold in childproof packaging is one way to reduce the incidence of poisonings, particularly among children. To date, in addition to the federal *Child Nicotine Poisoning Prevention Act of 2015* (2016) enacted in January 2016, more than a dozen states have enacted laws requiring childproof packaging for e-liquids (Tobacco Control Legal Consortium n.d.). Health care providers, the public health community, e-cigarette manufacturers and retailers, and the public should be aware that e-liquids pose a serious public health concern, particularly among young children.

Strategy 4B.

Coordinate, evaluate, and share best practices from state and local entities that have implemented programs and policies to address e-cigarette use among youth and young adults.

Many governments at the national, state, local, tribal, and territorial levels are involved in the regulation of e-cigarettes. To have the biggest impact on reducing the use and exposure of e-cigarettes among youth and young adults, it is integral for these governments to share best practices and coordinate and evaluate efforts as part of a comprehensive tobacco prevention and control strategy. FDA has asserted regulatory authority over e-cigarettes, and other agencies and governments, as discussed previously and in Chapter 5, also have relevant authorities.

Goal 5. Curb Advertising and Marketing That Encourages Youth and Young Adults to Use E-Cigarettes

Unconstrained marketing of e-cigarettes drives consumer demand for these products. E-cigarette manufacturers are using tactics similar to those used to market conventional cigarettes to youth, including offering candy-flavored products; employing youth-minded themes, such as rebellion, glamour, and sex; getting celebrity endorsements; and obtaining sports and music sponsorships (Chapter 4). Some groups have called for extending to e-cigarettes the same marketing restrictions that already apply to conventional cigarettes and other tobacco products (Association of State and Territorial Health Officials 2014; Partnership for Prevention 2014). But regulating commercial speech is typically met with significant barriers and complex legal issues (Laird-Metke 2010), and partial advertising bans and voluntary agreements generally have not been fully effective at reducing consumption because the tobacco industry adapts by shifting to other types of advertising that are not regulated (National Cancer Institute 2008). Despite these obstacles, public health organizations and state and local governments must take action to control the marketing of e-cigarettes to youth and young adults, including (a) seeking legally feasible interventions that are proven to curb youth-oriented tobacco marketing, including removing advertising from television; and (b) continuing to help build an evidence base that informs future potential restrictions on e-cigarette marketing.

Strategy 5A.

Curb e-cigarette advertising and marketing that are likely to attract youth and young adults.

In the absence or delayed implementation of government restrictions on the marketing of e-cigarettes, media outlets, the management staff of special event and sports venues, and retailers can voluntarily refuse to air or place youth- and young adult-oriented e-cigarette advertising; avoid sponsorships; and not offer free samples of these products at fairs, festivals, and other events.

E-cigarettes are aggressively marketed using tactics similar to those proven to lead to cigarette smoking among youth.

Finally, state and local public health agencies can stimulate enforcement of and compliance with existing rules that limit marketing. For example, they can monitor advertising and notify their state's attorney general or the Federal Trade Commission about improper claims or marketing that is not clearly identified as advertising (*Federal Register* 1972; FTC 1984; Center for Public Health and Tobacco Policy 2013).

Strategy 5B.

Urge the e-cigarette companies to stop advertising and marketing that encourages and glamorizes e-cigarette use among youth and young adults.

E-cigarette advertising has increased considerably over the years in multiple venues (Legacy for Health 2014; Ganz et al. 2015; see also Chapter 4), while the advertising for conventional cigarettes on television has been prohibited in the United States since 1971. But e-cigarettes are now marketed on television and other mainstream media channels, such as radio and magazines, which are main sources of information for youth and young adults. Emerging research suggests that exposure to television advertisements for e-cigarettes increases the likelihood that young people will use e-cigarettes in the future and will believe that e-cigarettes can be used in places where conventional cigarette smoking is not allowed (Farrelly et al. 2015). This is not surprising because e-cigarette marketing has previously included unproven claims about safety and smoking cessation, as well as statements that e-cigarettes are exempt from clean air policies that restrict smoking (USDHHS 2014). Visual depictions of e-cigarette use in advertisements may also serve as smoking cues to both current and former smokers, increasing their urges to smoke and undermining their efforts to quit (Maloney and Cappella 2015). Advertising for e-cigarettes that encourages and glamorizes the use of e-cigarettes among youth and young adults can harm public health by undermining:

- Clean indoor air standards;
- Enforcement of smokefree policies;
- Tobacco-free social norms; and
- Marketing restrictions that prohibit the advertising of cigarettes and smokeless tobacco on television and radio.

Discontinuing advertising and marketing by e-cigarette companies that intentionally or unintentionally encourages or glamorizes e-cigarette use among youth and young adults is essential. Responsible advertising by the e-cigarette companies is needed, including advertising that focuses directly on established adult smokers and features adults (not young adults), does not depict active use of e-cigarettes, does not use themes proven to appeal to youth and young adults, avoids media channels with high youth access, and does not undermine cessation efforts involving traditional tobacco products.

Goal 6. Expand Surveillance, Research, and Evaluation Related to E-Cigarettes

Tobacco control research focused on e-cigarettes has grown considerably in the past few years. Certainly, more detailed information is needed to better understand the use of e-cigarettes and its relationship to the use of other types of tobacco products. A comprehensive and evolving approach to research, surveillance, and evaluation is needed.

Strategy 6A.

Improve the quality, timeliness, and scope of e-cigarette surveillance, research, and evaluation.

Present surveillance systems show that e-cigarette use is increasing rapidly and that most regular e-cigarette users also use conventional tobacco products (see Chapter 2). Thus, further study can inform strategies that minimize harms and maximize the potential health benefits of these products at the individual and population levels. Data should be timely and focus on the patterns of e-cigarette initiation and use among the general public—including youth, young adults, and former smokers. Strategic and comprehensive research and evaluation must further characterize the health risks of e-cigarette use. A comprehensive package of surveillance, research, and evaluation should:

- Track patterns of e-cigarette use through cross-sectional surveys and through panels that follow the same people, including youth and young adults, over time;
- Monitor trends in the e-cigarette retail market by type of product;
- Examine the channels and messaging in the e-cigarette marketplace to inform proactive countermarketing strategies;

- Assess the short- and medium-term health effects of e-cigarette use by youth and young adults and track long-term consequences;
- Examine the risk factors and other risk behaviors that may be associated with using e-cigarettes; and
- Create a model to develop and track the public health impact of e-cigarettes.

The rapidly changing nature of the e-cigarette landscape calls for a comprehensive and evolving approach to research, surveillance, and evaluation.

For such a package, researchers, the public health community, and other key stakeholders must work together to address and overcome many challenges:

- The rapidly changing e-cigarette landscape and terminology;
- Limited resources for collecting timely information;
- The cross-sectional nature of existing surveys and their limited space for questions;
- The different populations that need to be studied;
- A lack of validated questions; and
- Different measures and definitions across surveys.

Strategy 6B.

Address surveillance, research, and evaluation gaps related to e-cigarettes.

Patterns of e-cigarette use are rapidly changing among youth and young adults, as well as among other groups in the population. Longitudinal data are not yet available to address some of the most critical issues related to e-cigarettes. The e-cigarette marketplace is changing so fast that surveillance data and research on the harms of e-cigarette use and the impact of these changes on traditional tobacco products are lagging behind. As they look to fill in gaps in scientific research, it is important for researchers to continue to seek more current and complete answers to many critical questions, such as:

- What are the risks of progressing to traditional tobacco use among youth and young adults who have used e-cigarettes?
- What are the health risks posed by e-cigarettes?
- Are e-cigarettes safer and more effective than current products at helping smokers with smoking cessation?
- What are the health consequences for youth and young adults of initiation of e-cigarettes and of dual use (conventional cigarettes plus e-cigarettes) compared with the health benefits of completely quitting smoking (or not starting at all)?
- What are the health risks to former smokers who are exposed to nicotine from e-cigarette use? Will these persons be more likely to resume smoking?

Additionally, surveillance of e-cigarette marketing and the advertising messages and strategies used is critical, as is the carrying out of more studies assessing the link between exposure to e-cigarette marketing and use of these products. With traditional tobacco

products, state and local public health agencies have monitored retail settings, assessed outdoor advertising, and identified sponsorships of events by tobacco companies. These efforts should be adapted to e-cigarettes.

The health care setting has always been an important venue for exchanging information about evidence-based approaches to smoking cessation and for protecting susceptible groups from exposure to secondhand smoke. More research is needed on the role of e-cigarettes in facilitating or hindering cessation of conventional cigarettes and the potential hazards of exposure to secondhand aerosol from e-cigarettes so that e-cigarettes can also be a part of this exchange. But even without this research, there is sufficient evidence about the dangers that nicotine-containing cigarettes pose for youth and young adults that health care providers and professionals can act now to prevent the use of such products among their young patients.

Finally, existing research and surveillance efforts should include more detailed measures than just general use of e-cigarettes, including:

- Frequency and patterns of e-cigarette use;
- Type of e-cigarette and/or other tobacco product used;
- The natural history of e-cigarette use, including initiation, co-use with other tobacco products, and flavoring;
- Ingredients, such as nicotine and flavors;
- Brand;
- Reasons for using and quitting e-cigarettes;
- Exposure to e-cigarette advertising;
- Methods of obtaining e-cigarettes; and
- Exposure to secondhand aerosol from e-cigarettes.

Additionally, evaluation is critical to further assess the impact of policies on e-cigarette initiation, use, and other patterns of tobacco use.

Conclusion

E-cigarette use, particularly among youth and young adults, has become a public health concern that warrants immediate and coordinated action. The increase in e-cigarette use among youth and young adults in the past few years is cause for great concern. Many questions remain about e-cigarettes and their long-term impact, even as evidence on patterns of use and risks to health continue to emerge. But we know enough about these health risks to take action now to protect the health of our nation's young people. We cannot wait. Strategies to prevent and control the harms of e-cigarettes among youth and young adults need to be precautionary. Therefore, we must take a precautionary approach by implementing these strategies and protecting the health of our nation's young people.

We know what works to effectively prevent tobacco use among young people. Now we must apply these strategies to e-cigarettes—and continue to apply them to other tobacco products. To achieve success, we must work together, aligning and coordinating efforts across a wide range of stakeholders. We must protect our nation’s young people from a lifetime of nicotine addiction and associated problems by immediately addressing e-cigarettes as an urgent public health problem. Now is the time to take action.

Chapter 358

ELECTRONIC CIGARETTES: U.S. IMPORTS IN 2016*

United States Government Accountability Office

The Honorable Ron Wyden
Ranking Member Committee on Finance
United States Senate

Dear Senator Wyden:

Over the last decade, use of electronic cigarettes, known as e-cigarettes, in the United States has grown rapidly as use of traditional cigarettes declined among both adolescents and adults. As we reported in May 2015, most e-cigarettes sold in the United States were thought to be imported, but e-cigarette import volume and tariff revenue were unknown because the Harmonized Tariff Schedule of the United States (HTS) did not contain separate statistical reporting numbers (also known as 10-digit HTS numbers or codes) specific to e-cigarettes.¹ Instead, imports of e-cigarette devices, e-cigarette parts, and e-cigarette liquid were entered under HTS statistical reporting numbers that the U.S. International Trade Commission (USITC) calls basket categories, which cover a range of goods.

An e-cigarette device typically contains a battery, a heating element, and a cartridge or tank that can be empty or filled with liquid. Major e-cigarette parts include heating elements and cartridges, which can be imported separately from devices. E-cigarette liquid—which can contain nicotine in different concentrations or have no nicotine—can also be imported separately from both devices and cartridges.

* This is an edited, reformatted and augmented accessible version of the United States Government Accountability Office Publication No. GAO-17-515R, dated April 24, 2017.

¹ GAO, *Electronic Cigarettes: Imports, Tariffs, and Data Collection*, GAO-15-491R (Washington, D.C.: May 7, 2015). All goods imported into the United States are classified by U.S. Customs and Border Protection according to the HTS. The HTS, published and maintained by the U.S. International Trade Commission, provides the legal basis for the classification of every product that enters the United States and the corresponding tariff rate the importer must pay for each product. The HTS contains numbered provisions at the 2-, 4-, 6-, 8-, and 10-digit level. The 10-digit provision is known as a statistical reporting number that can be used for tracking and reporting trade statistics.

In the fall of 2015, the Committee for Statistical Annotation of Tariff Schedules—comprising representatives from USITC, U.S. Customs and Border Protection (CBP), and the U.S. Census Bureau (Census)—established six new statistical reporting numbers for e-cigarette devices, parts, and liquid in the HTS. The six new statistical reporting numbers went into effect on January 1, 2016, and covered

- e-cigarette liquid that contains 5 percent or more by weight of nicotine (3824.90.2840) or less than 5 percent by weight of nicotine (3824.90.9280),²
- e-cigarette devices with cartridges that contain liquid with nicotine (8543.70.9630) or without nicotine (8543.70.9640),³ and
- e-cigarette parts, including cartridges imported separately from devices that contain liquid with nicotine (8543.90.8850) or without nicotine (8543.90.8860).

You requested that we report on e-cigarettes imported into the United States in 2016. We analyzed the e-cigarette import data for calendar year 2016, the first year such data were collected by the U.S. government. To analyze U.S. e-cigarette imports, we used 2016 data that were available in February 2017 from the public Interactive Tariff and Trade DataWeb database maintained by USITC, which incorporates U.S. trade statistics published by Census.⁴ We analyzed import data for the six statistical reporting numbers that covered e-cigarette devices, parts, and liquid in calendar year 2016. For each statistical reporting number, we analyzed customs value, dutiable customs value, tariff revenue, country of origin, and port of entry. We also analyzed data on quantities for the four e-cigarette statistical reporting numbers for which quantity is tracked.

U.S. import data are collected by CBP from records submitted by importers. These data are then incorporated into the official trade statistics published by Census. We used unrevised 2016 trade data. Census revises trade data periodically, and its first official revisions of 2016 trade data will be available in the summer of 2017.

To assess the reliability of the data, we reviewed agency documents about U.S. foreign trade statistics and interviewed CBP and Census officials about how the data were collected, how they were checked, and any limitations of the data. According to the officials we interviewed, the quality of trade data associated with new statistical reporting numbers improves over time both because the trade community learns to use them correctly and because Census is able to develop checks tailored for specific commodities or statistical reporting numbers. We determined that the 2016 data on U.S. e-cigarette imports that were available in February 2017 were sufficiently reliable for the purposes of presenting annual descriptive statistics but not for reporting monthly import data. We do not present monthly data in this report for the following reasons:

² Presidential Proclamation 9549 implementing international changes to the HTS, which took effect on January 1, 2017, resulted in the renumbering of HTS statistical categories 3824.90.2840 and 3824.90.9280 to 3824.99.2840 and 3824.99.9280, respectively.

³ Presidential Proclamation 9466, which took effect on July 1, 2016, resulted in the renumbering of HTS statistical categories 8543.70.9630 and 8543.70.9640 to 8543.70.9930 and 8543.70.9940, respectively. The units of quantity used for the new statistical categories were changed, enabling the tracking of the number of imported e-cigarette devices.

⁴ See <https://dataweb.usitc.gov/>.

- We observed an upward trend in overall customs value for U.S. e-cigarette imports in 2016. Based on our interviews with agency officials, we concluded that it is not yet known if the data reflect an actual trend or the importers' improved use of the new e-cigarette statistical reporting numbers over the course of 2016.
- We observed considerable monthly fluctuations in unit values (customs value divided by quantity) for e-cigarette liquid and devices. It is not yet known if these values are accurate or reflect data errors.
- We identified a notable error in the monthly data for one statistical reporting number. The 2016 data show a quantity for January 2016 for e-cigarette liquid containing less than 5 percent of nicotine by weight (classified under HTS number 3824.90.9280) that is more than 30 times the average value for the remaining months: 338,178 kilograms compared to the monthly average of 10,090 kilograms for February through December 2016. In response to our inquiries, CBP officials determined that this quantity was incorrect because of importer misclassification of some goods. According to Census officials, the corrected January 2016 data for HTS number 3824.90.9280 will be reflected in the revised 2016 data that will be released in the summer of 2017. The annual descriptive statistics we report for that e-cigarette product, and totals across all imported e-cigarette products, contain a value of zero for January, which we note in presenting the data.

We conducted this performance audit from January 2017 to April 2017 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

In summary we found the following:

- In calendar year 2016, customs value of U.S. e-cigarette imports was about \$342 million; of that amount, \$323 million was dutiable value resulting in about \$9 million in tariff revenue (see table 1). E-cigarette devices accounted for \$204 million (or almost 60 percent), parts for \$108 million (almost 32 percent), and liquid for \$30 million (almost 9 percent) of total customs value. Customs value is defined as the price actually paid or payable for merchandise when sold for exportation to the United States, excluding U.S. import tariffs (also known as duties), freight, insurance, and other charges incurred in bringing the merchandise to the United States. Dutiable value is defined as the customs value of foreign merchandise imported into the United States that is subject to tariff. In some cases, the dutiable value can be zero, if goods imported from a particular country are not subject to tariff.
- Although e-cigarettes, parts, and liquid were imported from 41 countries in 2016, e-cigarette imports from China accounted for about 91 percent of U.S. e-cigarette imports by customs value (see table 2). Imports from China also accounted for at least 98 percent of customs value for devices with nicotine and parts with and without nicotine (see table 3).

- In 2016, importers brought in 481,400 kilograms of e-cigarette liquid with higher nicotine content compared to 110,994 kilograms of liquid with lower nicotine content. From July through December 2016, importers brought in about 5.6 million e-cigarette devices with nicotine-containing liquid and about 5.3 million devices with nicotine-free liquid (see table 4).⁵
- U.S. e-cigarette imports cleared customs at 34 ports of entry; the top five ports of entry—Cleveland, Los Angeles, Savannah, Norfolk, and Seattle—accounted for 81 percent of customs value of U.S. e-cigarette imports in 2016 (see table 5).⁶

More detailed information is included in tables 1 through 5.

Table 1. Data Summary for U.S. e-cigarette imports in 2016

	E-cigarette product, Harmonized Tariff Schedule (HTS) number, and tariff rate	Customs value (dollars)	Dutiable customs value (dollars)	Tariff revenue (dollars)
Liquid ^a	E-liquid (nicotine content of 5 percent or more) HTS 3824.90.2840 Tariff rate: 6.5 percent of dutiable customs value	26,617,601	26,005,531	1,690,364
	E-liquid (nicotine content of less than 5 percent) ^b HTS 3824.90.9280 Tariff rate: 5 percent	2,888,820	2,684,570	134,249
	Subtotal for liquid	29,506,421	28,690,101	1,824,613
Devices ^c	Devices (imported with nicotine) HTS 8543.70.9630 (January–June 2016) HTS 8543.70.9930 (July–December 2016) Tariff rate: 2.6 percent	54,031,562	54,028,197	1,404,745
	Devices (imported without nicotine) HTS 8543.70.9640 (January–June 2016) HTS 8543.70.9940 (July–December 2016) Tariff rate: 2.6 percent	150,339,057	131,854,876	3,428,330
	Subtotal for devices	204,370,619	185,883,073	4,833,075
Parts ^d	Parts (imported with nicotine) HTS 8543.90.8850 Tariff rate: 2.6 percent (January–June 2016) 1.9 percent (July–December 2016)	26,302,044	26,275,168	584,030
	Parts (imported without nicotine) HTS 8543.90.8860 Tariff rate: 2.6 percent (January–June 2016) 1.9 percent (July–December 2016)	82,078,224	81,888,575	1,648,097
	Subtotal for parts	108,380,268	108,163,743	2,232,127
Total	Total	342,257,308	322,736,917	8,889,815

Source: GAO analysis of U.S. Census Bureau data as retrieved from the U.S. International Trade Commission's Interactive Trade DataWeb (accessed Feb. 9, 2017). | GAO-17-515R.

Notes: Customs value is defined as the price actually paid or payable for merchandise when sold for exportation to the United States, excluding U.S. import tariffs (also known as duties), freight, insurance, and other charges incurred in bringing the merchandise to the United States. Dutiable value is defined as the customs value of foreign merchandise imported into the United States that is subject to tariff.

^a According to the HTS, “mixtures for use in personal electric or electronic vaporizing devices means a formulated liquid, whether or not containing nicotine, and whether or not packaged for retail sale in cartridges or tanks adaptable to such devices” (see HTS ch. 38, statistical note 3). Ten-digit HTS number (also known as statistical reporting number) 3824.90.2840 covered e-cigarette liquid containing 5 percent or more by weight of nicotine; HTS number 3824.90.9280 covered liquid containing less than 5 percent by weight of nicotine. Presidential Proclamation 9549, which took effect on January 1, 2017, resulted in the renumbering of 3824.90.2840 and 3824.90.9280 to 3824.99.2840 and 3824.99.9280, respectively. Liquid quantity is tracked in kilograms.

^b In this table, the summary data for customs value, dutiable value, and tariff revenue for HTS number 3824.90.9280 cover the period from February through December 2016 because of an error in the January 2016 data. According to U.S. Census Bureau officials, the corrected January 2016 data for HTS number 3824.90.9280 will be reflected in the revised 2016 data that will be released in the

^c HTS numbers for devices cover both closed-system and open-system e-cigarettes if they are imported as functional devices with or without cartridges. The difference between the two sets of HTS numbers for devices is nicotine content. Presidential Proclamation 9466, which took effect on July 1, 2016, resulted in the renumbering of 8543.70.9630 and 8543.70.9640 to 8543.70.9930 and 8543.70.9940, respectively. The units of quantity used for the new HTS numbers were changed, enabling the tracking of the number of imported e-cigarette devices.

⁵ Quantities were tracked for e-cigarette liquid from January 1, 2016, and began to be tracked for e-cigarette devices on July 1, 2016.

⁶ The port of entry is where imported goods clear U.S. customs and may differ from the port of unloading where goods are unloaded from the importing vessel or aircraft.

Table 1. (continued)

^d HTS numbers for e-cigarette parts cover major parts, such as heating elements and cartridges containing heating elements, that are imported separately from e-cigarette devices. Smaller e-cigarette components—such as microprocessors, batteries, tubes containing batteries, or light-emitting diode lights—that may be used for other products in addition to e-cigarettes are classified under other applicable HTS provisions. The difference between the two statistical reporting numbers for e-cigarette parts is nicotine content of substances in cartridges. The tariff rate for e-cigarette parts was 2.6 percent of dutiable customs value from January 1 through June 30, 2016. The lower tariff rate of 1.9 percent took effect on July 1, 2016, as a result of Presidential Proclamation 9466. Quantity of e-cigarette parts is not tracked.

Table 2. Customs value of U.S. e-cigarette imports by country of origin in 2016

41 countries, in actual dollars

Country	Customs value ^a	
	Dollars	Percentage
China	313,009,762	91.45

Total	342,257,308	100.00

Source: GAO analysis of U.S. Census Bureau data as retrieved from the U.S. International Trade Commission's Interactive Trade DataWeb (accessed Feb. 9, 2017). | GAO-17-515R.

^a Country totals for customs value cover the entire calendar year 2016 for all e-cigarette Harmonized Tariff Schedule (HTS) numbers except HTS number 3824.90.9280. Customs value for HTS number 3824.90.9280 covers the period from February through December 2016 because of an error in the January 2016 data. According to U.S. Census Bureau officials, the corrected January 2016 data for HTS number 3824.90.9280 will be reflected in the revised 2016 data that will be released in the summer of 2017. The top 10 countries—China (including Hong Kong) through Switzerland—account for 99.5 percent of the total customs value of U.S. e-cigarette imports.

^b The United States does not have diplomatic relations with Taiwan; the data we used list Taiwan as a country and break out imports from Taiwan separately.

Table 3. Customs value of U.S. e-cigarette imports by country of origin and product in 2016

41 countries, in millions of dollars

Country	Liquid		Devices		Parts		Total by country

Total by product	26.618	2.889	54.032	150.339	26.302	82.078	342.257

Source: GAO analysis of U.S. Census Bureau data as retrieved from the U.S. International Trade Commission Interactive Trade DataWeb (accessed Feb. 9, 2017). | GAO-17-515R.

Notes: The top 10 countries—China (including Hong Kong) through Switzerland—account for 99.5 percent of the total customs value of U.S. e-cigarette imports. See table 2 for a complete list of countries. The numbers may not add up precisely because of rounding.

^a Harmonized Tariff Schedule (HTS) number 3824.90.2840—replaced with 3824.99.2840 on January 1, 2017—covered e-cigarette liquid containing 5 percent or more by weight of nicotine.

^b HTS number 3824.90.9280—replaced with 3824.99.9280 on January 1, 2017—covered e-cigarette liquid containing less than 5 percent by weight of nicotine. In this table, customs value for HTS number 3824.90.9280 covers the period from February through December 2016 because of an error in the January 2016 data. According to U.S. Census Bureau officials, the corrected January 2016 data for HTS number 3824.90.9280 will be reflected in the revised 2016 data that will be released in the summer of 2017.

^c HTS number 8543.70.9930—which replaced 8543.70.9630 on July 1, 2016—covers e-cigarette devices imported with cartridges filled with liquid containing nicotine.

^d HTS number 8543.70.9940—which replaced 8543.70.9640 on July 1, 2016—covers e-cigarette devices imported with cartridges filled with nicotine-free liquid.

^e HTS number 8543.90.8850 covers major e-cigarette parts, including cartridges containing heating elements and filled with liquid containing nicotine, that are imported separately from devices.

^f HTS number 8543.90.8860 covers major e-cigarette parts, including cartridges containing heating elements and filled with nicotine-free liquid, that are imported separately from devices.

Table 4. Quantity and customs value of e-cigarette liquid and devices imported into the United States in 2016

Liquid	Quantity (kg)	Customs value (dollars)
Liquid with 5 percent or more of nicotine (January–December) ^a	481,400	26,617,601
Liquid with less than 5 percent of nicotine (February–December) ^b	110,994	2,888,820
Devices	Quantity (number)	Customs value (dollars)
Devices with nicotine (July–December) ^c	5,637,744	26,066,916
Devices without nicotine (July–December) ^d	5,311,204	97,867,572

Source: GAO analysis of U.S. Census Bureau data as retrieved from the U.S. International Trade Commission's Interactive Trade DataWeb (accessed Feb. 9, 2017). | GAO-17-515R

Notes: Tracking of quantity of imported e-cigarette liquid took effect on January 1, 2016; tracking of quantity of imported e-cigarette devices began on July 1, 2016.

^a Harmonized Tariff Schedule (HTS) number 3824.90.2840—replaced with 3824.99.2840 on January 1, 2017—covered e-cigarette liquid containing 5 percent or more by weight of nicotine.

^b HTS number 3824.90.9280—replaced with 3824.99.9280 on January 1, 2017—covered e-cigarette liquid containing less than 5 percent by weight of nicotine. In this table, quantity and customs value for HTS number 3824.90.9280 cover the period from February through December 2016 because of an error in the January 2016 data. According to U.S. Census Bureau officials, the corrected January 2016 data for HTS number 3824.90.9280 will be reflected in the revised 2016 data that will be released in the summer of 2017.

^c HTS number 8543.70.9930—which replaced 8543.70.9630 on July 1, 2016—covers e-cigarette devices imported with cartridges filled with liquid containing nicotine.

^d HTS number 8543.70.9940—which replaced 8543.70.9640 on July 1, 2016—covers e-cigarette devices imported with cartridges filled with nicotine-free liquid.

Table 5. Customs value of U.S. e-cigarette imports by port of entry in 2016

34 ports of entry, in actual dollars

Port of entry	Customs value ^a	
	Dollars	Percentage
Cleveland, OH	83,828,226	24.49

Notes: The port of entry is where imported goods clear U.S. customs and may differ from the port of unloading where goods are unloaded from the importing vessel or aircraft.

^a Port-of-entry totals for customs value cover the entire calendar year 2016 for all e-cigarette Harmonized Tariff Schedule (HTS) numbers except HTS number 3824.90.9280. Customs value for HTS number 3824.90.9280 covers the period from February through December 2016 because of an error in the January 2016 data. According to U.S. Census Bureau officials, the corrected January 2016 data for HTS number 3824.90.9280 will be reflected in the revised 2016 data that will be released in the summer of 2017.

Chapter 359

ELECTRONIC CIGARETTES: U.S. IMPORTS, 2016-2018*

United States Government Accountability Office

The Honorable Ron Wyden Ranking Member
Committee on Finance United States Senate

Dear Senator Wyden:

Over the last 15 years, use of electronic cigarettes, known as e-cigarettes, in the United States has grown rapidly as use of traditional cigarettes declined among both adolescents and adults. As we reported previously, most e-cigarettes sold in the United States are thought to be imported.¹ The U.S. government began collecting data specific to e-cigarette imports in January 2016, after the Committee for Statistical Annotation of Tariff Schedules established six new statistical reporting numbers for e-cigarette devices, parts, and liquid in the Harmonized Tariff Schedule of the United States (HTS).² In April 2017, we reported, on the basis of the first year of data, that the customs value of U.S. e-cigarette imports in 2016 was

* This is an edited, reformatted and augmented version of United States Government Accountability Office, Accessible Version, Publication No. GAO-19-619R, dated July 12, 2019.

¹ GAO, *Electronic Cigarettes: U.S. Imports in 2016*, GAO-17-515R (Washington, D.C.: Apr. 24, 2017).

² The committee comprises representatives from the U.S. International Trade Commission (USITC), U.S. Customs and Border Protection (CBP), and the U.S. Census Bureau. All goods imported into the United States are classified by CBP according to the HTS. The HTS, published and maintained by USITC, provides the legal basis for the classification of every product that enters the United States and the corresponding tariff rate the importer must pay for each product. The HTS contains numbered provisions at the 2-, 4-, 6-, 8-, and 10-digit level. The 10-digit provision is known as a statistical reporting number that can be used for tracking and reporting trade statistics. For more information about the committee and process for establishing new statistical reporting numbers, see GAO, *Electronic Cigarettes: Imports, Tariffs, and Data Collection*, GAO-15-491R (Washington, D.C.: May 7, 2015).

about \$342 million and that 91 percent of those imports, by customs value, came from China.³

You requested that we report on e-cigarettes imported into the United States from 2016 through 2018. This report examines the customs value, tariff revenue, countries of origin, and ports of entry for e-cigarette devices, parts, and liquid imported during those years. We analyzed the data that were available in April 2019 from the Interactive Tariff and Trade DataWeb maintained by the U.S. International Trade Commission (USITC), which incorporates U.S. trade statistics published by the U.S. Census Bureau (Census).⁴ We analyzed import data for the six statistical reporting numbers that covered e-cigarette devices, parts, and liquid in 2016 through 2018.⁵ For each reporting number, we analyzed customs value, tariff revenue, country of origin, and port of entry.⁶ We also analyzed data on import quantities for four e-cigarette reporting numbers—covering e-cigarette devices and liquid—for which the federal government tracked quantity in 2016 through 2018.⁷

To understand trends in the data and assess the data's reliability, we reviewed agency documents about U.S. foreign trade statistics and interviewed U.S. Customs and Border Protection (CBP) and Census officials about how the data were collected, how they were checked, and any limitations of the data. We determined that the data were sufficiently reliable for the purposes of presenting annual descriptive statistics.

We conducted this performance audit from April to July 2019 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence we obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

An e-cigarette device typically contains a battery, a heating element, and a cartridge or tank that may be empty or filled with liquid. Major e-cigarette parts include heating elements and cartridges, which can be imported separately from devices. E-cigarette liquid—which may contain nicotine in different concentrations or no nicotine—can also be imported separately from both devices and cartridges.

As Table 1 in the enclosure shows, the six statistical reporting numbers in the HTS for U.S. e-cigarette imports cover devices with and without nicotine; parts with and without nicotine; and two types of nicotine-containing e-cigarette liquid: (1) liquid mixtures containing 5 percent or more by weight of one or more aromatic or modified aromatic

³ GAO-17-515R. Customs value is defined as the price actually paid or payable for merchandise when sold for exportation to the United States, excluding U.S. import tariffs (also known as duties), freight, insurance, and other charges incurred in bringing the merchandise to the United States.

⁴ See <https://dataweb.usitc.gov/>.

⁵ All years cited in this report are calendar years (January–December). U.S. import data are collected by CBP from records submitted by importers. These data are then incorporated into the official trade statistics published by Census. We used unrevised 2018 trade data. Census revises trade data periodically, and its first official revisions of 2018 trade data became available in June 2019, after we completed our analysis. Throughout this report, our analysis is based on consumption import data, which measure the total of merchandise that has physically cleared U.S. customs, either entering consumption channels immediately or entering after withdrawal for consumption from bonded warehouses or foreign trade zones under CBP custody.

⁶ To report tariff revenue, we used the “calculated duty” variable, which represents the estimated import duties collected. Estimated duties are calculated on the basis of the applicable rate(s) of duty (or tariff) as shown in the HTS.

⁷ Tracking of the quantity of imported e-cigarette liquid began in January 2016 and of e-cigarette devices in July 2016. Tracking of the quantity of imported e-cigarette parts began in January 2019.

substances, including nicotine (liquid with higher aromatic substance content), and (2) liquid mixtures containing less than 5 percent by weight of one or more aromatic or modified aromatic substances, including nicotine (liquid with lower aromatic substance content).⁸ Devices with and without nicotine are subject to the same general tariff rate, and parts with and without nicotine are subject to the same general tariff rate. However, liquid with higher aromatic substance content is subject to a higher general tariff rate (6.5 percent of customs value) than liquid with lower aromatic substance content (5 percent of customs value).⁹

In summary, our analysis of U.S. e-cigarette import data for 2016 through 2018 found the following:

- **Customs value and tariff revenue for all U.S. e-cigarette imports.** The customs value of e-cigarette devices, parts, and liquid imported into the United States from 2016 through 2018 was \$2.4 billion (see Table 2 in the enclosure). Devices and parts each accounted for about \$1.2 billion of total customs value (48 percent for each, or 96 percent for both) and liquid accounted for \$101.5 million (4 percent). The federal government collected \$120 million in total tariff revenue from these imports during this period.
- **Changes in customs value, tariff revenue, and quantities of U.S. e-cigarette imports from 2016 to 2018.** The customs value of all U.S. e-cigarette imports increased by 300 percent from 2016 to 2018 (see Table 3 in the enclosure). The customs value of five of the six imported e-cigarette products—devices with and without nicotine, parts with and without nicotine, and liquid with lower aromatic substance content—increased from the 2016 level to the 2018 level. Tariff revenue from these products also increased (see Table 4 in the enclosure). In addition, quantities of imported devices with and without nicotine and of liquid with lower aromatic substance content increased (see Table 5 in the enclosure). Only imported e-cigarette liquid with higher aromatic substance content decreased in customs value, tariff revenue, and quantity from the 2016 level to the 2018 level.

⁸ These descriptions for the two types of e-cigarette liquid, corresponding to statistical reporting numbers 3824.99.2840 and 3824.99.9280, reflect recent discussions with U.S. International Trade Commission and U.S. Customs and Border Protection officials and differ from the descriptions presented in our prior related report (GAO-17-515R). In that report, the descriptions for e-cigarette liquid, developed in consultation with officials from the same agencies, distinguished between the two statistical reporting numbers on the basis of nicotine content. The two statistical reporting numbers each cover nicotine-containing formulated liquid mixtures and are distinguished from each other by the percentage of aromatic or modified aromatic substances, including nicotine, and not by the percentage of nicotine alone. Formulated liquid mixtures imported under 3824.99.2840 and 3824.99.9280 may also contain other substances in addition to aromatic and modified aromatic substances. For more information, see table 1 in the enclosure.

⁹ General tariff rates are applied to imported goods from countries with which the United States has normal trade relations.

Source: GAO analysis of U.S. Census Bureau data retrieved from the U.S. International Trade Commission's Interactive Trade DataWeb (accessed Apr. 29, 2019). | GAO-19-619R.

Notes: See Table 3 in GAO-19-619R for a more detailed presentation of the data for these imports.

The descriptions for the two types of nicotine-containing e-cigarette liquid, corresponding to statistical reporting numbers 3824.99.2840 and 3824.99.9280, reflect recent discussions with U.S. International Trade Commission and U.S. Customs and Border Protection officials and differ from the descriptions presented in our prior related report (GAO-17-515R). In that report, the descriptions for e-cigarette liquid, developed in consultation with officials from the same agencies, distinguished between the two statistical reporting numbers on the basis of the percentage of nicotine content. The two statistical reporting numbers each cover nicotine-containing formulated liquid mixtures; are distinguished from each other by the percentage of aromatic or modified aromatic substances, including nicotine; and may also contain other substances.

Figure 1. Customs value of e-cigarette devices, parts, and liquid imported into the United States, 2016-2018.

As Figure 1 and Table 3 in the enclosure show, the highest increases in customs value from the 2016 level to the 2018 level were associated with imported parts without nicotine (684 percent), liquid with lower aromatic substance content (582 percent), and parts with nicotine (322 percent). In addition, the customs value of imported devices without nicotine increased by 231 percent during this period. By comparison, the customs value of imported liquid with higher aromatic substance content decreased by 28 percent from 2016 to 2018.

- U.S. e-cigarette imports by country.** The customs value of e-cigarette imports from China accounted for 97 percent of the customs value of all e-cigarette imports from 65 countries from 2016 through 2018 (see Table 6 in the enclosure). Imports from China accounted for almost 100 percent of the customs value of all devices with nicotine and 95 percent of the customs value of all devices without nicotine (see Table 7 in the enclosure) and for about 99 percent of the customs value of all parts with and without nicotine (see Table 8 in the enclosure). Devices and parts without

nicotine were imported from a larger number of countries than devices and parts with nicotine. In contrast to devices and parts, e-cigarette liquid imported from China represented a smaller percentage of the customs value of the two types of imported e-cigarette liquid: 90 percent for liquid with higher aromatic substance content and 69 percent for liquid with lower aromatic substance content (see Table 9 in the enclosure).

Our analysis of quantities of e-cigarette devices and liquid imported from 2016 through 2018 shows similar patterns. From July 2016 through December 2018, e-cigarette importers brought 271 million e-cigarette devices with and without nicotine into the United States. Almost all imported devices with and without nicotine, or just under 100 percent by quantity, came from China (see Table 10 in the enclosure). From January 2016 through December 2018, e-cigarette importers brought 2 million kilograms of nicotine-containing e-cigarette liquid into the United States. Liquid with higher aromatic substance content imported from China accounted for 55 percent of all such imported liquid by quantity, and liquid with lower aromatic substance content imported from China accounted for 45 percent (see Table 11 in the enclosure).

- **Ports of entry.** The top five ports of entry—Los Angeles, Cleveland, Chicago, Savannah, and Norfolk—accounted for 81 percent of the customs value of U.S. e-cigarette imports in 2016 through 2018 (see Table 12 in the enclosure).¹⁰ Notably, the value of e-cigarette imports that cleared customs at the Chicago port of entry increased 80-fold, from about \$6 million in 2016 to \$468 million in 2018.

ENCLOSURE – 1

Table 1. HTS classification summary for U.S. e-cigarette imports, January 2016–June 2019

E-cigarette product and statistical reporting number	General tariff rate (percentage of customs value)	Unit of quantity	Date when tracking of quantity began
Devices ^a			
Devices with nicotine 8543.70.9930 ^b	2.6 percent	Number	July 2016
Devices without nicotine 8543.70.9940 ^b	[+25 percent additional tariff rate since August 23, 2018, for products from Chinac]		
Parts ^a			
Parts with nicotine 8543.90.8850 ^d	2.6 percent (Jan. 2016–June 2016) 1.9 percent (July 2016–June 2017) 1.3 percent (July 2017–June 2018) 0.6 percent (July 2018–June 2019) ^e	Number	January 2019
Parts without nicotine 8543.90.8860 ^d	[+10 percent additional tariff rate since September 24, 2018, for products from China that increased to 25 percent on May 10, 2019 ^c]		

¹⁰ The port of entry is the location where imported goods clear U.S. customs and may differ from the port of unloading, where goods are unloaded from the importing vessel or aircraft.

E-cigarette product and statistical reporting number	General tariff rate (percentage of customs value)	Unit of quantity	Date when tracking of quantity began
Liquid^f			
Liquid mixtures containing 5 percent or more by weight of one or more aromatic or modified aromatic substances, including nicotine (liquid with higher aromatic substance content) 3824.99.2840 ^g	6.5 percent [+10 percent additional tariff rate since September 24, 2018, for products from China that increased to 25 percent on May 10, 2019 ^c]	Kilogram	January 2016
Liquid mixtures containing less than 5 percent by weight of one or more aromatic or modified aromatic substances, including nicotine (liquid with lower aromatic substance content) 3824.99.9280 ^g	5 percent [+10 percent additional tariff rate since September 24, 2018, for products from China that increased to 25 percent on May 10, 2019 ^c]		

Source: GAO presentation of information from the Harmonized Tariff Schedule of the United States (HTS) and U.S. International Trade Commission. | GAO-19-619R.

Notes: General tariff rates are applied to imported goods from countries with which the United States has normal trade relations. The HTS also enumerates tariff rates for goods from some of these countries that qualify for preferential tariff rates under a variety of special trade agreements as well as rates for a specific list of countries. The HTS additionally lists special tariff rates for products that fit technical specifications enumerated in notes to the HTS. See the HTS for these other rates.

Customs value is defined as the price actually paid or payable for merchandise when sold for exportation to the United States, excluding U.S. import tariffs (also known as duties), freight, insurance, and other charges incurred in bringing the merchandise to the United States.

^aAccording to the HTS (chapter 85, statistical note 7), for the purposes of statistical reporting numbers 8543.70.9930, 8543.70.9940, 8543.90.8850, and 8543.90.8860, personal electric or electronic vaporizing devices are devices that electrically heat or atomize liquids or other substances, whether or not containing nicotine, producing a vapor to be inhaled through the mouthpiece.

^bStatistical reporting numbers 8543.70.9930 and 8543.70.9940 replaced 8543.70.9630 and 8543.70.9640, respectively, on July 1, 2016. These reporting numbers cover closed-system and open-system e-cigarettes if they are imported as functional devices with or without cartridges.

^cThe additional tariffs were imposed by the U.S. Trade Representative (USTR) in accordance with the direction of the President. On August 18, 2017, following a Memorandum from the President, USTR initiated an investigation under Section 301 of the Trade Act of 1974 into the government of China's acts, policies, and practices related to technology transfer, intellectual property, and innovation. 82 *Fed. Reg.* 40,213 (Aug. 24, 2017). As a result of the investigation and at the direction of the President, USTR imposed tariffs on a range of products from China in three separate actions in 2018. See, 83 *Fed. Reg.* 28,710 (June 20, 2018); 83 *Fed. Reg.* 40,823 (Aug. 16, 2018); and 83 *Fed. Reg.* 47,974 (Sept. 21, 2018). Additionally, effective May 10, 2019, USTR increased the tariff rate imposed on products covered by its third action from 10 percent to 25 percent. The additional tariffs are effective until suspended or terminated.

^dStatistical reporting numbers 8543.90.8850 and 8543.90.8860 cover major parts, such as heating elements and cartridges containing heating elements, that are imported separately from e-cigarette devices. Smaller e-cigarette components—such as microprocessors, batteries, tubes containing batteries, or light-emitting diode lights—that may be used for other products in addition to e-cigarettes are classified under other applicable HTS provisions.

^eThe general tariff rate of 0.6 percent was reduced to zero on July 1, 2019.

^fAccording to the HTS (chapter 38, statistical note 3), for the purposes of statistical reporting numbers 3824.99.2840 and 3824.99.9280, “mixtures for use in personal electric or electronic vaporizing devices” means a formulated liquid containing nicotine, whether or not packaged for retail sale in cartridges or tanks adaptable to such devices.

^gIn this report, the descriptions of the two types of e-cigarette liquid, corresponding to statistical reporting numbers 3824.99.2840 and 3824.99.9280, reflect recent discussions with U.S. International Trade Commission and U.S. Customs and Border Protection officials and differs from the descriptions presented in our prior related report (GAO-17-515R). In that report, the descriptions for e-cigarette liquid, developed in consultation with officials from the same agencies, distinguished between the two reporting numbers on the basis of nicotine content. The two statistical reporting numbers each cover nicotine-containing formulated liquid mixtures and are distinguished from each other by the percentage of aromatic or modified aromatic substances, including nicotine, and not by the percentage of nicotine alone. Formulated liquid mixtures imported under 3824.99.2840 and 3824.99.9280 may also contain other substances—such as, for example, glycol or glycerin—in addition to aromatic and modified aromatic substances. Statistical reporting numbers 3824.99.2840 and 3824.99.9280 replaced 3824.90.2840 and 3824.90.9280, respectively, on January 1, 2017.

Source: GAO analysis of U.S. Census Bureau data retrieved from the U.S. International Trade Commission's Interactive Trade DataWeb (accessed Apr. 29, 2019). | GAO-19-619R.

Notes: Tracking of the quantity of imported e-cigarette liquid began in January 2016 and of e-cigarette devices in July 2016. Tracking of the quantity of imported e-cigarette parts began in January 2019.

^aThe descriptions for the two types of nicotine-containing e-cigarette liquid, corresponding to statistical reporting numbers 3824.99.2840 and 3824.99.9280, reflect recent discussions with U.S. International Trade Commission and U.S. Customs and Border Protection officials and differ from the descriptions presented in our prior related report (GAO-17-515R). In that report, the descriptions for e-cigarette liquid, developed in consultation with officials from the same agencies, distinguished between the two statistical reporting numbers on the basis of the percentage of nicotine content. The two statistical reporting numbers each cover nicotine-containing formulated liquid mixtures; are distinguished from each other by the percentage of aromatic or modified aromatic substances, including nicotine; and may also contain other substances.

Note: The port of entry is the location where imported goods clear U.S. customs and may differ from the port of unloading, where goods are unloaded from the importing vessel or aircraft.

Chapter 360

ELECTRONIC CIGARETTE FIRES AND EXPLOSIONS IN THE UNITED STATES 2009 - 2016*

Lawrence A. McKenna Jr.

MISSION STATEMENT

We provide national leadership to foster a solid foundation for our fire and emergency services stakeholders in prevention, preparedness and response.

Key Points

- The combination of an electronic cigarette and a lithium-ion battery is a new and unique hazard. There is no analogy among consumer products to the risk of a severe, acute injury presented by an e-cigarette.
- Fires or explosions caused by the batteries used in electronic cigarette are uncommon; however the consequences can be devastating and life-altering for the victims.
- It is likely that the number of incidents and injuries will continue to increase.
- Since the current generation of lithium-ion batteries is the root cause of these incidents, it is clear that these batteries are not a safe source of energy for these devices.
- Between January 2009 and December 31, 2016, 195 separate incidents of explosion and fire involving an electronic cigarette were reported by the U.S. media. These incidents resulted in 133 acute injuries. Of these injuries, 38 (29 percent) were severe.
- To date, there have been no deaths in the United States caused by electronic cigarette fires or explosions.
- One hundred and twenty-one (62 percent) of the incidents of explosion and fire involving an electronic cigarette or its battery occurred when the device was either in a pocket or actively in use.
- The shape and construction of electronic cigarettes can make them (more likely than other products with lithium-ion batteries) behave like “flaming rockets” when a battery fails.
- Lithium-ion batteries must be charged in accordance with the manufacturer’s instructions.

* This is an edited, reformatted and augmented version of U.S. Fire Administration, dated July 2017.

UPDATED REPORT

This report is an update to the report “Electronic Cigarette Fires and Explosions” published by the U.S. Fire Administration (USFA) in October 2014. Data on electronic cigarette incidents that occurred in the U.S. between September 2014 and December 2016 have been added to the data reported in the previous report for this analysis. Any additional incidents that occurred prior to September 2014 and discovered during this literature survey were included in the data reported herein.

A considerable number of incidents and severe injuries is reported, as well as the revelation of a previously unrecognized hazardous condition — electronic cigarette and battery explosions in pockets.

WHAT IS AN E-CIGARETTE

The term “electronic cigarette” encompasses a whole class of devices with many different shapes and configurations. In this report, the term “e-cigarette” will be used generically to refer to any or all e-cigarettes, e-cigs, personal vaporizers (PVs), electronic nicotine delivery systems (ENDS), mods, or similar devices.

E-cigarettes are battery-powered devices which simulate tobacco smoking by producing a heated vapor that resembles smoke. These devices have become very popular as an alternative to smoking, including with a growing number of individuals who have never been smokers, but who enjoy the many flavors and/or the experience of using e-cigarettes.

Development

E-cigarettes were first patented in 2003, and have been available for sale in the U.S. since 2007. E-cigs have been rapidly growing in popularity as the number and selection of products expand at an extremely rapid pace. Zhu, et al. (2014) report that by January 2014, there were 466 brands of e-cigarettes and 7,764 unique flavors available for sale. They also state that the number of products has been increasing at a rate of 10.5 brands and 242 new flavors per month. StatisticBrain¹ reports that there were 2,750,000 e-cigarette smokers in America and sales of e-cigarette devices and accessories in America exceeded \$2.8 billion in 2015. Indicators point to continued dynamic growth in the industry.

What Do They Look Like? How Much Do They Cost?

E-cigarette designs vary greatly. Some resemble a traditional cigarette, cigar or pipe, while others resemble a flashlight, or a small pack of cigarettes with a protruding tube. Cell phone cases with built-in e-cigarettes are also available. Figure 1 shows three common, commercially available devices.

¹ <http://www.statisticbrain.com/electronic-cigarette-statistics>.

Figure 1. Three of the many e-cigarette styles available.

Prices for the devices range from \$30 to over \$300, with a corresponding range in battery size, liquid capacity, and vapor output. The most basic device is an electronic cigarette, which looks like a traditional cigarette. Moving up the line, devices designed to make larger quantities of vapor are often called PVs or mods. Users can purchase a wide variety of commercially available devices or can make their own. Homemade vaporizers and e-liquids are common.

How Do They Work?

The devices have an electric heating element (an atomizer or cartomizer) to vaporize a liquid solution. Solutions (also called juice) usually contain a mixture of propylene glycol (increases flavor), vegetable glycerin (increases vapor), nicotine, and flavorings. Some juices provide flavored vapor without nicotine. Figure 2 shows the principal parts that are found in every e-cigarette or vaporizer.

Figure 2. Parts of an electronic cigarette.

“Automatic” e-cigarettes activate the heating coil when a user takes a drag from the device. Manual e-cigarettes have a switch that the user depresses to energize the heating element to make the heated vapor. Most manufactured devices have built-in timeout features that prevent overheating, and many have locking features to prevent the switch from being activated in a pocket or purse. An LED light to simulate cigarette glow on the end is present in some e-cigarettes, but is not common in PVs or mods.

Alternate Uses

E-cigarettes are sometimes used to smoke hash oil or “honey oil,” a cannabis product derived by separating the resins from marijuana. Separating hash oil from marijuana is a hazardous process, sometimes done illegally in hotels and homes. First responders should be aware that this practice exists and the hazards that it presents.²

Health and Safety

The health effects of the vapor and the danger of nicotine overdose by ingestion or dermal contact with the juice are the subject of ongoing review by various agencies (Cressey, 2014, World Health Organization (WHO), 2014). The regulatory situation related to e-cigarettes varies by jurisdiction and is rapidly changing. At the time of publication of this report, the following facts were known:

- On May 10, 2016, the U.S. Food and Drug Administration (FDA) issued a final rule that brought e-cigarettes under the FDA’s tobacco product authority. With this rule making, FDA now regulates the manufacture, import, packaging, labeling, advertising, promotion, sale, and distribution of e-cigarettes. At the time this report was prepared, the FDA had extended the compliance deadline until August 10, 2017.
- The WHO has proposed that member states adopt stringent controls on e-cigarettes (2014). The proposal is limited to the potential health effects of e-cigarettes, and does not include language addressing the electronics.
- American Nonsmoker’s Rights Foundation (2017) reports that 12 states and 615 local jurisdictions have laws restricting e-cigarette use in smoke-free venues; 15 states and 503 local jurisdictions have laws that restrict e-cigarette use in other venues.
- Underwriters Laboratories (UL) has developed standards that relate to lithium-ion battery safety. These standards are applied to products containing batteries that undergo UL safety testing. In early 2017, UL promulgated UL Standard 8139, Electrical Systems of Electronic Cigarettes, which evaluates only the battery and electrical controls of an electronic cigarette.
- No current regulation, code, or law applies to the safety of the electronics or batteries in e-cigarettes. While many consumer products are required to be tested by a

² For more information see: <http://www.rmhidta.org/default.aspx/MenuItemID/691/MenuGroup/RMHIDTAHome.htm>.

Nationally Recognized Test Laboratory, such as UL, there are no requirements that e-cigarettes be subjected to product safety testing. The FDA is considering regulations of the battery or electronics used in/with the devices (FDA, 2014; Ledford, 2014).

METHODOLOGY

Why Did We Look at E-Cigarettes?

A number of explosions and fires have been attributed to e-cigarettes, causing some concern within the fire service community. We conducted this review to gather information to inform first responders and other interested parties about the scope and nature of the problem.

Data Sources

Authoritative data on the occurrence of e-cigarette fires and explosions is not easy to find. The National Fire Incident Reporting System (NFIRS) does not include specific data fields on e-cigarettes that will permit the typical analysis of the frequency or impact of these incidents. Concurrent with the publication of the 2014 edition of this report, the USFA issued an advisory on how to code an e-cigarette incident in an NFIRS report³. The data cited in this report includes e-cigarette incidents reported in the NFIRS.

It has been recognized that many fires are never reported to the fire department. Fires that self-extinguish, or those that are easily extinguished by persons nearby, are frequently not reported. The 2014 report showed that the majority of e-cigarette fires fall into this category of self- or easily-extinguished. As such, few are reported in the NFIRS database.

As was done in the previous study, media reports were used to collect information on e-cigarette incidents. The internet was searched using a variety of relevant terms and multiple search engines to locate media reports on incidents of interest. Incidents were logged, and the reports were carefully reviewed to eliminate duplicate reports and to extract data of interest. Due to the newsworthy nature of the more severe incidents, there were often multiple reports on a single incident, with occasionally conflicting information. Every effort was made to eliminate duplication and redundancy.

There may be other data sources that could shed additional light on the topic. Data from emergency-room visits and/or hospital admissions could be informative. Similarly, we are aware of emergency medical system databases that could be mined for relevant data. Due to time constraints and other factors, these data sources were not queried for the present analysis.

In light of these constraints on the availability of data, and in light of the quality of that data, the information presented herein is qualitative rather than quantitative. Readers are advised to use the results appropriately.

³ USFA, NFIRSGram: Coding an electronic cigarette fire, https://www.usfa.fema.gov/data/nfirs/support/nfirsgrams/nfirsgram_electronic_cigarettes.html.

FINDINGS

Overview

Reports of 195 separate e-cigarette fire and explosion incidents in the U.S. were found, dating from January 2009 to Dec 31, 2016. In 68 percent of these incidents, 133 acute injuries were reported. No deaths were reported during the study period. A summary spreadsheet of the incidents reported is included in Appendix 2 for reference.

Figure 3 shows the status of the e-cigarettes at the time the incidents occurred.

- Sixty-one incidents occurred when either the device or spare batteries for the device were in a pocket.
- Sixty incidents occurred while the device was being used.
- Forty-eight incidents occurred while the battery in the device was being charged.
- Eighteen incidents occurred while the device or battery was stored.
- In seven incidents, it is not reported whether the e-cigarette was in use, stored, or being charged.
- One incident occurred during transportation on a cargo aircraft.

Figure 3. Status of e-cigarette when the incident occurred.

Media reports generally characterize these incidents as explosions. While there is generally a brief period of overheating and off-gassing at the onset of the event, the events tend to occur suddenly, and are accompanied by loud noise, a flash of light, smoke, flames, and often vigorous ejection of the battery and other parts. A number of the media reports state that the battery or other components of the device were ejected under pressure and “flew across the room,” often igniting combustible items where they landed.

Injuries

In 133 (68 percent) of the reported fire and explosion incidents involving e-cigarettes, a single individual was injured.⁴ Figure 4 illustrates the number and severity of injuries in e-cigarette fires and explosions.

Figure 4. Injuries reported in e-cigarette incidents.

- Thirty-eight of the incidents resulted in severe injury to an individual, meaning that the victim required hospitalization, and may have suffered loss of a body part, 3rd degree burns, or facial injuries.
- Eighty victims suffered moderate injuries, which were defined as persons requiring treatment in the emergency room for smoke inhalation, 2nd degree burns, or lacerations requiring stitches. Typically, incidents reported as moderate injuries did not require admission to the hospital.
- Fifteen individuals suffered minor injuries, including smoke inhalation, minor lacerations, or 1st degree burns. Emergency room treatment may or may not have been provided.
- No injuries were reported in 62 (32 percent) of the incidents.

The incidents involving severe injuries occurred while the e-cigarette device was in the victim's mouth, in very close proximity to their face, on in a pocket. This inherent intimacy with the device is what makes the e-cigarette hazard unique among consumer products. No other consumer product that is typically used so close to the human body contains the lithium-ion battery that is the root cause of the incidents.

Did the Fires Spread?

Of the reported fire and explosion incidents involving e-cigarettes, 128 (66 percent) resulted in ignition of nearby contents such as clothing, carpets, drapes, bedding, couches, or vehicle seats. Users were generally nearby when the incident occurred, were alerted by the sound of the explosion, and were able to take action to extinguish the fires while they were still small. Figure 5 shows the distribution of fire spread due to e-cigarette incidents.

⁴ Press in the United Kingdom has reported one death in an August 2014 incident where an e-cigarette that was being charged in a non-manufacturer approved device exploded and ignited nearby oxygen equipment.

Figure 5. Fire spread in e-cigarette fire and explosion incidents.

- In 91 incidents, the fire spread was minor, meaning that the scorching or flames either self-extinguished or were extinguished very quickly by persons nearby. Typically, in these incidents, the burned areas were 6 inches or less in diameter.
- In 27 incidents, the fire spread was moderate, where the burned area was larger than 6 inches in diameter, but the fire was extinguished by occupants before the fire department arrived.
- In 10 incidents, the fire spread was major and involved significant portions of a building, and required suppression by the fire department. Typically, these incidents are what the fire service refers to as “room and contents” type fires, or larger.
- In 67 of the incidents (34 percent), there was no fire spread, or fire spread was not evident in the reports reviewed.

How the Fires Were Suppressed

The battery in the e-cigarette contains a limited amount of combustible material. If the burning battery and/or e-cigarette comes into contact with a material that is easily ignited, such as bedding or clothing, a fire can easily spread and grow. The media reports were reviewed to determine how the ensuing fires were suppressed; the results are shown in Figure 6.

Figure 6. How e-cigarette fire incidents were suppressed.

- In 168 incidents, the fires either self-extinguished or were extinguished very quickly by persons nearby.
- In 18 incidents, the fire department performed final suppression of the fire.
- In 8 incidents, the mode of fire suppression was not reported.
- In 1 incident, an automatic fire suppression system extinguished the fire.

Trends

Figure 7 and Figure 8 show that the number of e-cigarette fires and explosions is increasing over time. An increase in the number of e-cigarette fires and explosions was postulated in the 2014 report and appears to correlate well with the increase in sales of e-cigarettes.

Figure 9 illustrates the increasing number of severe and moderate injuries resulting from e-cigarette explosions and fires. Note the increase in number of severe injuries since 2014. This appears to correlate well with the e-cigarette sales trend shown in Figure 8.

Figure 7. Number of e-cigarette fires and explosions.

E-cigarette sales data from <http://www.statisticbrain.com/electronic-cigarette-statistics/> on 3/27/2017.

Figure 8. E-Cigarette fires and explosions compared to sales.

Figure 9. Incidence of severe and moderate injuries from e-cigarette explosions and fires.

Always use the charging appliance that comes with the unit, and follow the manufacturer’s instructions. Plugging an e-cigarette into a “standard” USB port to recharge may result in an explosion and/or fire.

A NEW AND UNIQUE HAZARD TO CONSUMERS

The e-cigarette/lithium-ion battery combination presents a new and unique hazard to consumers. No other consumer product places a battery with a known explosion hazard such as this in such close proximity to the human body. It is this intimate contact between the body and the battery that is most responsible for the severity of the injuries that have been seen. While the failure rate of the lithium-ion batteries is very small, the consequences of a failure, as we have seen, can be severe and life-altering for the consumer.

Responsible battery and e-cigarette manufacturers are working hard to develop remedies for the known lithium-ion battery failures. Indeed, good and successful solutions have been put into production by responsible manufacturers. Unfortunately, the manufacturers cannot control what modifications are made by the consumer, or what replacement battery is installed into the e-cigarette by the consumer. The impact of safety features on consumer safety can be dampened by consumer behavior.

Spare Batteries

Many consumers purchase spare batteries so they can vape through the day without having to recharge batteries. Many vape shops sell plastic cases to store and carry the spare batteries; these are intended to prevent a battery short-circuit (and the ensuing explosion) if the terminals of the battery come into contact with keys or spare change in a pocket. As noted above, the device or battery in a pocket was the leading status of the e-cigarette at the time of the incident (Figure 3).

Users procure spare batteries from a number of sources. Some purchase spare batteries with their device in the anticipation that the battery will be compatible with the protection circuitry in the device. Others will salvage lithium-ion batteries from old laptop computers or power tool battery packs. While salvaged batteries can be essentially free, few users

understand that such batteries rarely have protective circuitry built in, since robust protective circuitry is typically integrated into the battery pack and/or the original device. Still other users purchase spare batteries from a variety of sources.

A quick search of online sales or auction sites will show thousands of listings for 18650 batteries, a lithium-ion battery frequently used in e-cigarettes and many other consumer devices. Most of the listings will highlight the energy capacity in milli-amp hours (mAh) of the battery being offered; typical listings vary from 2,500 mAh to 6,000 mAh. Many consumers will gravitate to the higher capacity batteries to gain the longest use. Unfortunately, many of these claims are unsubstantiated or misleading. The space inside the case of every 18650 battery for the battery components is the same, and the capacity varies considerably depending on the current draw.

Similarly, many of the online listings will claim that a battery is “protected” or “has protection,” implying protection against overcharging, overheating, or other deleterious events. While the manufacturer may (or may not) be placing a protection circuit in the battery, there is generally little technical information available about this “protection” that even an advanced user could access.

Do It Yourself

Further compounding the safety situation is the fact that a substantial number of e-cigarette users either construct their own devices from widely available parts or modify commercial products to suit their desires. Since the data reviewed in preparing this report do not provide sufficient information to permit any conclusion about how many of the incidents reported involved homemade or modified devices, it is not possible to draw valid conclusions about how these practices could be impacting the incidence of fires.

There are a number of sites on the internet that provide instructional material on how to safely construct or modify a device. Many vape shops also offer advice and instruction for the do-it-yourself vaper. The quality of the instruction and advice available varies widely, and even the best of those that were reviewed in the preparation of this report are incomplete in that they overlook elements of battery/system safety or rely on poorly-documented system components. Without a proper engineering analysis, neither purchasing a battery that has “protection,” nor adding a generic “protection circuit” to a device, can be a guarantee that the desired level of protection will be provided.

Safety Standards

UL has recently promulgated UL Standard 8139, *Electrical Systems of Electronic Cigarettes*. This new test standard will evaluate the safety of the electrical and battery systems of e-cigarettes, in the hope that fires and explosions resulting from the battery and electrical system can be eliminated.

It is important to understand what UL8139 will not do. UL advises that,

“These requirements do not cover the consumable of the electronic cigarette, such as e-Liquids and other inhaled vapor substances, wicks, and other particulate matter inhaled during use. These requirements do not consider the physiological effects of any consumable used with the product.”

Most Americans are familiar with the UL listing mark and look for this certification when purchasing electrical products. E-cigarettes that are UL-listed using this new test standard should provide a level of assurance of safety to consumers that has not been available before. However, this assurance is not absolute, since manufacturing defects and damage to the product can still occur.

This new UL standard is an important development in the safety of these devices and should serve to reduce the number of e-cigarette fires and explosions, as well as the number of injuries that American consumers have experienced from these products.

CONCLUSION

E-cigarettes using lithium-ion batteries present a new and unique hazard to consumers. No other consumer product places a battery with a known explosion hazard such as this in such close proximity to vital areas of the human body. In order to reduce the frequency of e-cigarette fires and explosions, the following recommendations should be considered:

- Consumers should look for and demand e-cigarette products that have been evaluated for safety and that are listed by UL. Look for the UL mark on the product and packaging.
- The long-term effects of the new UL safety standard cannot be determined at this time. Even with improved protection circuitry in an e-cigarette device, and with 100 percent compliance in providing such protection, there remains a possibility of battery failure and severe injury. Manufacturing defects and damage to the device or battery simply cannot be eliminated.
- Lithium-ion batteries should not be used in e-cigarettes. While the number of batteries that explode and catch fire is statistically small, the catastrophic nature of the injuries that can occur warrants the use of another battery technology for e-cigarettes.
- As long as lithium-ion batteries continue to be used in e-cigarettes, severe injuries will continue to occur. As the number of e-cigarettes in use increases, the number of

severe injuries from lithium-ion battery explosions and fires will likely continue to increase.

- Suppliers, industry associations, user groups, and fire prevention educators should all stress the importance of using UL-listed devices and proper charging practices to reduce the number of incidents. Stronger warnings in the literature and user manuals may be helpful.

APPENDIX 1: A PRIMER ON LITHIUM-ION BATTERY FAILURE IN E-CIGARETTES

Lithium-ion-polymer (Li-ion) batteries are excellent power supplies for portable devices and are widely used by consumers, industry, and the emergency services. Li-ion batteries are known to experience statistically rare failure events, including fire and explosions (Mikolajczak, Kahn, White & Long, 2011). Indeed, there are multiple reports of fires caused

by failures of Li-ion batteries in cell phones, laptop computers, medical devices, electric cars, power tools, hoverboards, and a myriad of other electronic devices.

Why Do Li-Ion Batteries Catch Fire?

A cylindrical Li-ion battery is made by winding alternating layers of metallic anode and cathode material separated by a porous film. The porous separator film holds a liquid electrolyte made of an organic solvent and dissolved lithium salts. This core is placed into a cylindrical metal can through the open end, and the can is then sealed tightly closed so that the liquid electrolyte cannot escape or evaporate.

All of the electrolytes currently used in Li-ion batteries are either flammable or combustible liquids. It is this flammable electrolyte that causes the fire and explosion when the Li-ion battery overheats.⁵ Scientists are working to develop nonflammable electrolytes for Li-ion batteries, but these are not yet available in the market.

During the typical failure mode for a Li-ion battery, the electrolyte is heated to its boiling point.⁶ The internal pressure in the battery builds to a point where the seal at the end of the battery ruptures, and the pressure is abruptly released through the sealed end of the battery case. Usually, the electrolyte then ignites, and expanding gas from the rapid combustion will further increase the pressure. The fire is sustained briefly after initial ignition by the porous separator film, which is made of plastic. Mikolajczak, et al. (2011) provide detailed descriptions and explanations of the various failure modes that Li-ion batteries can experience. A number of videos showing Li-ion battery ignition can be easily found on the internet.

Why Is the Impact of Battery Failure Different in E-Cigarettes?

E-cigarettes are different from other electronic consumer devices because the battery is installed in a cylindrical device (the e-cigarette) that has its weakest (structural) point at the ends. When the battery seal (at the end of the battery) ruptures, the pressure within the e-

⁵ A variety of organic solvents are used, alone or in combinations. The boiling points of the electrolytes range from 200°F to 500°F, and ignition temperatures range from 60°F to 300°F.

⁶ Overheating of the battery (thermal runaway) can be caused by: puncture, overcharge, external heat, short circuit, or internal cell fault.

cigarette cylinder builds quickly until it ruptures, usually at the end. As a result of the battery and container failure, one or the other, or both, can be propelled across the room like a bullet or small rocket.

In contrast to e-cigarettes, the cylindrical Li-ion batteries used in laptop computers and portable tools are contained in rigid plastic cases that are generally strong enough to prevent the failing battery from rocketing away. Fires do occur as a result of battery failure, but most fires initially involve only the device that the battery pack is installed in.⁷

Cell phones, tablets, and other devices use pouch-type Li-ion batteries that are flat, rather than cylindrical in shape, and are encased in a sealed flexible plastic pouch or rigid plastic case instead of a metal can. These pouch-type batteries will not build up much pressure when they overheat and do not explode violently when they fail. Pouch batteries can, and have, overheated to the point where the pouch bursts, the electrolyte ignites and a fire spreads beyond the device.⁸

What Safeguards Are Used to Prevent Fires in Li-Ion Batteries?

Several different approaches to protecting Li-ion batteries against explosion or fire have been developed. Protection can be built into the battery, into the charging appliance, or into the electronics that control the charging cycle and/or the current draw. Often, a combination of these approaches is used in a product. Amon, Andersson, Karlson, and Sahlin (2012) conclude that the risk of fire depends heavily on the type and effectiveness of the protection system used.

The protection appropriate for a particular device or appliance is determined by the device manufacturer, and/or by regulations or standards that apply to that product. Since there are no regulatory standards directly applicable to e-cigarettes, the selection of protection for the Li-ion battery is left to the manufacturers' best judgment. The fact that, statistically, so few of these devices are failing in the ways described in the media reports suggests that e-cigarette manufacturers have been largely successful in preventing battery fires.

⁷ A laboratory experiment showing worst-case Li-ion battery failures in a laptop computer can be seen at <https://www.youtube.com/watch?v=pizFsY0yjs#t=250>.

⁸ Failure of an intentionally overloaded pouch-type Li-ion battery can be seen at https://www.youtube.com/watch?v=SMY2_qNO2Y0&index=8&list=PLkLKD6x5giq2LyjhKbJt-OYR8kiAN8_UW.

APPENDIX 2: E-CIGARETTE FIRES AND EXPLOSION INCIDENTS

E-cigarette incidents reviewed						
Date	Location	Status	Fire beyond e-cig?	Injuries?	Extinguished	Notes
Aug 2009	Minneapolis, MN	Transport	Moderate	None	System	Fire in a cargo container on a FedEx® jet discovered during approach to landing. Fire suppression system activated. Fire was linked to lithium-ion batteries in box of Ruyan inhalers, model RappE-Mystick.
Nov 2011	Greeley, CO	Use	No	Severe	Self or occupant	A man was hospitalized for eight days after an electronic cigarette exploded in his face, sending burning debris and battery acid into his mouth, face and eyes. Prodigy V3.1 e-cig cited, as well as Radio Shack Energell battery.
Feb 2012	Niceville, FL	Use	No	Severe	Self or occupant	E-cigarette explodes in mouth causing severe burns, lost teeth and part of tongue. Lots of press coverage on this one. Some stories report that the device may have been modified by the user.
Apr 2012	Muskogee, OK	Use	No	None	Self or occupant	New e-cig exploded when withdrawn from packaging.
Nov 2012	Sherman, TX	Charge	No	Moderate	Not reported	Battery into two-hour charge exploded in users hand. Second and third degree burns on hand and smoke inhalation.
Apr 2013	Glendale, AZ	Charge	Moderate	None	Self or occupant	Exploded while charging from USB adaptor in car. Hot fragments ignited back seat upholstery.
Apr 2013	Oklahoma City, OK	Storage	Moderate	Minor	Not reported	Explosion of lithium-ion battery in e-cig in office. Occupant treated for inhalation.
Jul 2013	Corona, CA	Charge	Minor	Moderate	Self or occupant	Charging in car led to "blowtorch" fire and explosion. Debris flew into occupant's lap, resulting in second degree burns on upper thighs and lower buttocks. Driver used coffee to extinguish the fire.

E-cigarette incidents reviewed						
Date	Location	Status	Fire beyond e-cig?	Injuries?	Extinguished	Notes
Jul 2013	Oklahoma City, OK	Charge	Minor	None	Self or occupant	Device exploded and shot across the room 15 minutes after being plugged into charger. Bum marks on carpet and wall.
Jul 2013	Tulsa, OK	Charge	Minor	Not Reported	Not reported	Fire while charging off laptop.
Jul 2013	Claremont, CA	Storage	Moderate	Moderate	Self or occupant	E-cigarette charging in car overheated and exploded. Parts landed in female occupant's lap and caused burns. Reported second degree burns on back of upper thighs and lower buttocks.
Aug 2013	Oklahoma City, OK	Charge	Minor	None	Self or occupant	Device exploded while being charged.
Aug 2013	Phoenix, AZ	Charge	Minor	None	Self or occupant	This one ignited carpet, was put out by resident. Video shows plugging into white laptop for charge.
Aug 2013	Phoenix, AZ	Charge	Major	Minor	Fire department	Resident states in article that e-cig started two fires in their bedroom in recent days. They just exploded. Charging for about 20 minutes. First incident scorched carpet, second gutted the bedroom. Resident treated for smoke inhalation. (Smokin Time brand cited.)
Sep 2013	Grant Park, GA	Charge	Minor	None	Self or occupant	Device exploded during charging, shooting flame across the room. Scorch mark on couch, hole burned in carpet. Occupant used a rag to control.
Sep 2013	Binghamton, NY	Charge	Moderate	None	Fire department	Fire in home caused by charging e-cig.
Sep 2013	Provo, UT	Charge	Moderate	Moderate	Self or occupant	Explosion while charging in car. Hot fragments ignited baby's car seat in back seat resulting in first and second degree burns to 3 year old. Driver used iced coffee to extinguish fire.

Date	Location	Status	Fire beyond e-cig?	Injuries?	Extinguished	Notes
Jul 2013	Oklahoma City, OK	Charge	Minor	None	Self or occupant	Device exploded and shot across the room 15 minutes after being plugged into charger. Bum marks on carpet and wall.
Jul 2013	Tulsa, OK	Charge	Minor	Not Reported	Not reported	Fire while charging off laptop.
Jul 2013	Claremont, CA	Storage	Moderate	Moderate	Self or occupant	E-cigarette charging in car overheated and exploded. Parts landed in female occupant's lap and caused burns. Reported second degree burns on back of upper thighs and lower buttocks.
Aug 2013	Oklahoma City, OK	Charge	Minor	None	Self or occupant	Device exploded while being charged.
Aug 2013	Phoenix, AZ	Charge	Minor	None	Self or occupant	This one ignited carpet, was put out by resident. Video shows plugging into white laptop for charge.
Aug 2013	Phoenix, AZ	Charge	Major	Minor	Fire department	Resident states in article that e-cig started two fires in their bedroom in recent days. They just exploded. Charging for about 20 minutes. Appendix 2. (Continued)

E-cigarette incidents reviewed						
Date	Location	Status	Fire beyond e-cig?	Injuries?	Extinguished	Notes
Oct 2013	La Crosse, WI	Charge	Minor	Not Reported	Self or occupant	Story highlights several incidents during charging. Lack of overcurrent/ overhear circuitry implicated.
Oct 2013	Valparaiso, FL	Charge	Moderate	None	Self or occupant	Explosion while charging from USB port, igniting curtains. Occurred after 10 minutes charging.
Oct 2013	Blaine, MN	Charge	Minor	None	Self or occupant	Exploded and shot across the room while charging on USB plugged into computer. Carpet burned in several spots.
Nov 2013	Kootenai County, ID	Charge	Moderate	None	Self or occupant	Explosion while charging from USB port of laptop. Ignited couch. Smoke alarm alerted the sleeping family of four.
Nov 2013	Warren, MI	Charge	Minor	None	Self or occupant	Device blew out of wall socket in ball of fire. Scorched hardwood flooring before occupant extinguished it. TV video report shows a USB wall charger that does not match those supplied by the manufacturer (Bulldog brand cited).
Nov 2013	Eugene, OR	Charge	Moderate	None	Not reported	Device failed after about two hours charging. Fragments flew to back seat, igniting seat of truck.
Nov 2013	Queen Creek, AZ	Charge	Minor	None	Self or occupant	Exploded while charging, shooting across the room. Impacted window, fell to floor and ignited carpet.
Nov 2013	Colorado Springs, CO	Charge	Moderate	Moderate	Self or occupant	Unattended while charging on floor. Ignited bed. Home occupant burned arms, hands and face while using blanket to smother flames.
Dec 2013	Salt Lake City, UT	Charge	Minor	None	Self or occupant	E-cig exploded while being charged through USB port on a computer.

E-cigarette incidents reviewed							
Date	Location	Status	Fire beyond e-cig?	Injuries?	Extinguished	Notes	Source URL
Dec 2013	Springfield, MO	Charge	Moderate	Moderate	Self or occupant	Failure while charging on laptop USB port. Ignited bedding, second degree burns on leg and foot. User quoted as saying he likely used the wrong charger.	Original story accessed October 2014 from www.ky3.com (Springfield MO) has been removed.
Dec 2013	Salt Lake City, UT	Charge	Minor	None	Self or occupant	Device exploded while being charged. Shot across the room; minor burn marks.	http://fox13now.com/2013/12/09/e-cigarette-explodes-while-charging/
Dec 2013	Phoenix, AZ	Charge	Major	None	Fire department	E-cig being charged exploded on bed, igniting room and contents.	http://www.abc15.com/news/local-news/investigations/ phoenix-fire-department- officials-wam-electronic-cigarette-users-about-fire-danger
Jan 2014	Sneads Ferry, NC	Use	No	Minor	Self or occupant	Device erupted in his face. Temporary blindness, minor burns to face.	http://www.jdnews.com/20140111/man-injured-after-e-cig-blows-up/301119030
Mar 2014	Medford, OR	Charge	Minor	None	Self or occupant	Exploded while being charged, sending bits of burning battery flying into the ceiling and walls. One hot piece of battery landed on a pillow, causing it to smolder and filling the house with smoke.	http://www.katu.com/news/ local/Fire-marshal-e-cigarette- batteries-cause-fires-in- Medford-248274331.html
Mar 2014	Medford, OR	Charge	Minor	None	Self or occupant	The lithium batteries that power the vaporizers in electronic cigarettes caused two recent fires in Medford. In this second case, a mattress caught fire, but a resident put it out.	http://www.katu.com/news/ local/Fire-marshal-e-cigarette- batteries-cause-fires-in- Medford-248274331.html
Mar 2014	Lompoc, CA	Charge	Moderate	None	Self or occupant	Started kitchen fire while charging unattended.	Original story accessed October 2014 from www.ksby.com (San Louis Obispo, CA) has been removed.
Mar 2014	Syracuse, NY	Not reported	Moderate	Severe	Self or occupant	Patient on oxygen in a hospital suffered first and second degree burns. Patient had e-cig, but investigation has not yet tied e-cig to the ignition. Hospital has banned e-cigs out of caution. Patient transferred to area burn unit.	http://www.foxnews.com/us/2014/04/22/ny-hospital- reinforces-ban-after-e-cigarette- fire/

Appendix 2. (Continued)

E-cigarette incidents reviewed						
Date	Location	Status	Fire beyond e-cig?	Injuries?	Extinguished	Notes
Apr 2014	Goffstown, NH	Charge	Minor	None	Self or occupant	Resident reported to fire department that e-cigarette was left in bedroom to charge. Shortly thereafter, resident heard a loud bang and on investigating discovered a small fire in the carpet of the bedroom. Resident extinguished the fire and found e-cigarette pieces on the carpet.
Apr 2014	Destin, FL	Use	No	Severe	Self or occupant	Vape blew up in his face. Dime-sized hole in the roof of his mouth. Burns to hand, fractured neck and finger, burns to cornea, damaged teeth.
May 2014	Orlando, FL	Charge	Minor	None	Self or occupant	Resident heard a loud bang in bedroom where e-cigarette was charging and discovered carpet on fire when she investigated. Resident extinguished the fire.
Jul 2014	Oklahoma City, OK	Charge	Major	None	Fire department	Device exploded while being charged. Ignited home fire.
Jul 2014	Lawrenceville, NJ	Charge	Major	None	Self or occupant	E-cigarette left unattended for two plus hours in an aftermarket charger in a vehicle failed and started fire in rear seats. Windows were closed, so fire self-extinguished; sedan interior was extensively damaged.
Aug 2014	Boston, MA	Storage	Minor	None	Self or occupant	E-cigarette packed in checked luggage ignited in the baggage hold of a commercial airliner before takeoff. Burned a "small hole" in the bag.
Sep 2014	Honolulu, HI	Charge	Minor	None	Fire department	Unattended charging via typical AC USB adaptor. Occupant returned to find kitchen counter and contents burning. Occupant extinguished the fire and called fire department.
Nov 2014	College Park, MD	Use	inor	None	Fire department	A sparking e-cigarette was discarded into a university trash can, igniting the contents. Fire department responded and extinguished the fire. No damage beyond the trash.

Appendix 2. (Continued)

E-cigarette incidents reviewed						
Date	Location	Status	Fire beyond e-cig?	Injuries?	Extinguished	Notes
Feb 2015	Ramona, CA	Use	No	Severe	Fire department	Authorities responded to the Stage Stop Liquor Store in Ramona Sunday evening after an e-cigarette exploded, burning an employee and damaging the store. Materials from the e-cigarette cut the man's face and shattered a glass display inside the store, the captain said. Victim was hospitalized with facial burns.
Feb 2015	Anaheim, CA	Use	No	Minor	Not reported	Witnesses told police that the 17-year-old boy was holding an electronic cigarette in the moments before the explosion. Victim suffered cuts and burns to his hand.
Feb 2015	CA	Use	No	Severe	Self or occupant	When victim brought the device up to his face to see if it was making the hissing sound, it exploded. The tank hit him in the face, the mouth piece blasted through his cheek leaving a ragged hole, and the bottom of the tank blew off and caught fire. A nearby curtain, blanket and chair caught fire. Second degree burns to face, ear and neck, also broken cheekbone and concussion.
Mar 2015	Gates, NY	Use	Minor	Moderate	Not reported	MOD failed 30 seconds after battery was inserted. Victim required about six stitches to close hand laceration.
Mar 2015	Santa Ana, CA	Use	No	Minor	Not reported	Victim was smoking a MOD e-cigarette about 1:45 a.m. Treated for flash burns to face and hand, and lacerations to the hand.

Chapter 361

CHARACTERIZATION AND ABUSE OF ELECTRONIC CIGARETTES: THE EFFICACY OF “PERSONAL VAPORIZERS” AS AN ILLICIT DRUG DELIVERY SYSTEM*

Michelle Peace, PhD and Joseph Turner, PhD

STATEMENT OF PROBLEM

Electronic cigarettes (e-cigarettes or e-cigs), known as “personal vaporizers” (PV) by avid users or electronic nicotine delivery systems (ENDS) by industry, have experienced a significant increase in popularity for those seeking an alternative to smoking traditional tobacco products. These products are comprised of a battery-powered atomizer and a cartridge filled with a pharmaceutical (nicotine), flavorings, and water dissolved in glycerol products. E-cigarette are manufactured in a variety of options: from off-the-shelf non-customizable devices to customizable, including self-wrapping of the element, homemade wicks, self-preparation of the e-cigarette liquid formulation (e-liquids), cups to hold plant material, dripping vs wicking, and wattage adjusters to administer the desired drug.

The lack of enforced regulation prior to May 2016 has resulted in easy accesses to e-cigarettes and has shepherded their nefarious uses. The use of the e-cigarettes as an illicit drug delivery device is touted on websites, forums, blogs, and videos describing how best to use them for specific illicit drugs such as tetrahydrocannabinol, methamphetamine, fentanyl, and heroin. These sites explain at length the benefits of “vaping” illicit drugs as it can conceivably be done in public without attracting notice. While some individuals and communities have begun to legislate where users can vape, vaping is not just acceptable, it is considered “cool” by many and often has the added benefit of no odor.

Analyzing paraphernalia for drug usage uses straightforward methodology established in controlled substance laboratories nationwide. E-cigarettes were largely uncharacterized at the

* This is an edited, reformatted and augmented version of Office of Justice Programs’ National Criminal Justice Reference Service, Document No. 251788, dated June 2018.

beginning of this research. In forensic science laboratories, little is known or understood about their construction, let alone how they are used to deliver illicit drugs. From a general toxicological perspective, little is documented regarding the delivery of nicotine, particularly as a function of power, for e-cigarettes. Even less is known regarding the adulteration of e-cigarettes and how the e-cigarettes are used or modified to optimize the delivery of an adulterant and/or alternative drug.

Problems can arise with using electronic cigarettes to deliver illicit drugs. According to the vaping community, the dosing can be increased by turning up the wattage/voltage on the device. This method to increase dosage alone, or combined with increasing the volume of the “puff,” could easily lead to overdoses. Increasing temperatures could lead to pyrolysis products which can potentially be used as biomarkers that could identify the use of e-cigarettes in biological tissues and which may have unknown biological effects. Drug forums are providing cautionary tales to users, however, these are overshadowed by the clear benefits these devices bring to drug users.

Few peer-reviewed published manuscripts in the literature describe, define, and/or illustrate the use of e-cigarettes. The overarching purpose for this study was to characterize the use and efficacy of electronic cigarettes to deliver pharmaceutical products. E-cigarettes were functionally described, methods were developed to analyze the pharmaceutical products (e-liquids and aerosol), truth in advertising was described for commercially available products, adulterations to the products were assessed, and potential biomarkers were evaluated.

IMPLICATIONS FOR CRIMINAL JUSTICE POLICY AND PRACTICE

What Is the Impact of the Project on the Criminal Justice System?

Significant efforts have been made to educate law enforcement, medical examiners, toxicologists, and crime lab practitioners about drug use and abuse employing e-cigarettes. Public awareness has increased as to the potential dangers, and crime scene investigators and death investigators have reported collecting these and sending them to crime labs. Ultimately, this study has provided greater understanding in the court systems nationwide as to the nature of drug usage, abuse, and overdose cases in which e-cigarettes were used to deliver an illicit drug.

We believe that the impact to the criminal justice system is slowly unfolding. However, the research group has been asked to speak at national and international conferences to continue to educate scientists and crime scene investigators as to the potential impact of using e-cigarettes illicitly. Dr. Peace, the PI, has been invited to numerous conferences to present our findings, and will be providing information directly to the DEA who now has significant interest in the adoption of e-cigarettes. Additionally, the research group has been interviewed for news outlets such as *New Scientist* and NPR's *With Good Reason*. This kind of broader exposure will benefit the criminal justice system from an immediate general awareness perspective to, hopefully, programmatic/systemic changes.

How Has It Contributed to Crime Laboratories?

Given that one role of the forensic toxicologist is to define and characterize drug usage trends, this publicly funded research posed an important, relevant, and critically timed study to address an identified threat to public health and criminal justice. This research supported the analytical efforts in controlled substances units and will support the findings and opinions of scientists, medical examiners, death investigators, and forensic toxicologists as they present analytical results.

As of April 24, 2017, the research group has been consulted on seven e-cigarette cases. One case involved a professional athlete who submitted to a urine drug test and tested positive for a banned substance. He reported that he vaped from someone else's e-cigarettes, that contained an e-liquid purchased from a retail shop that was not labeled as having contained that substance. The laboratory who conducted the testing called to inquire about the feasibility of this claim. Based on our analyses of dozens of samples of e-liquids purchased from multiple vendors, the story was plausible. Three cases involved samples submitted through emergency room departments. One sample was determined to contain apomorphine and nuciferine, found in blue lotus flowers. Two cases involved potential overdose deaths. In the first, witnesses claimed that the victim vaped from an e-cigarette and died shortly thereafter. Analysis of the e-cigarette and e-liquid revealed no drug besides nicotine. One case involved a family-based litigation case in which someone claimed to be "just vaping" while illicit substances were found in the e-cigarette. And lastly, a "smoke easy" raid was conducted in a Philadelphia warehouse in which 22 people were arrested for marijuana possession and distribution. According to an analyst in the crime laboratory, the evidence collected included dozens of cartridges presumably containing cannabinoids. The analyst had attended the two webinars produced by the Center of Excellence on our research, and, as a result, was assigned the e-cigarette evidence. The research group will collaborate with that crime laboratory to analyze the products seized.

What Is the Impact on Technology Transfer?

In addition to providing critical information at an important time in the emergence of these products, the study has supported the efforts to understand the e-cigarette industry by regulatory agencies such as the FDA. Given that most of the knowledge of "puff topography," or the volume of cloud, duration of the inhale, and the concentration of drug in the cloud, is promulgated by users, this research has contributed to the scientific foundation for electronic e-cigarette usage.

Recently, the research group was asked to provide presentations and our list of publications to the U.S. Food and Drug Administration and to U.S. Department of the Navy, which is evaluating whether or not to ban e-cigarettes on submarines. So, while the impact on the criminal justice system is evolving, significant implications exist in other forums.

DESIGN METHODS AND RESULTS

The following aims and experiments were identified within the proposal. Within each, specific experimental goals and results are described.

In addition to pursuing these aims, we also monitor the current state of e-cigarette usage, messaging in the media, and legislation and regulation.

Goal: The goal was to identify information and resources to assist ongoing research to understand the forensic impact and implications of e-cigarettes. Information gleaned in the process of this study will assist decision-making regarding criminal justice and public education.

- Modifications and adulterations to electronic cigarettes and e-liquids, including illicit drug delivery, are described and promulgated by experienced users through videos, social media, and user blogs.
- All fifty states have developed policy in at least one of these five areas: sales to minors, defining e-cigarettes as tobacco products, bans on use in public, taxes, or other regulations.
- Media has reported deaths due to e-liquid consumption.
- Over the course of the 2+ year project, drug forum conversations evolved rapidly to discuss modifications and adulterations to e-cigarettes and e-liquids.
 - Recent conversations have included drugs such as Kratom (mitragynine), synthetic cannabinoids, synthetic opioids, and blue lotus (apomorphine and nuciferine)
 - Natural products in addition to illicit substances continue in the threads.
 - New e-cigarettes models emerged for the specific use of waxes, dabs, and dry natural products.
 - Modifications to the atomizers, mostly with regards to coil configurations, escalated as e-cigs became more technologically advanced.
 - Users continued to advocate regularly, despite prohibitions to public vaping, that the ease of transporting illicit substances and vaping illicit substances in public was a bonus for adopting the method.
- After the FDA banned the sale of products, websites had to stand-up a screening process to make sure that people were >18 years old. We monitored the complexity of this and have been challenged by more reputable websites who have questioned the identity of the purchaser. Since the credit card had the university address, the vendor was unable to “confirm” identity and age of the purchaser. Vendors with questionable e-liquid products have had no problem with the disconnect between the address of the credit card and our identity. While there is no way to know without further investigation, the difference between the two types of vendors has been observed.
- An evaluation of historical patents was performed to create a timeline of e-cigarettes and their mechanisms for operation, particularly as their construction evolves.

Aim 1

Develop reliable, validated analytical methods to support the efficient and thorough analysis of e-cigarette devices, device components, and aerosol for pharmaceuticals in adulterated, unadulterated, and self-prepared formulations.

Experiment 1. Develop method for capturing vapor product from electronic cigarettes by water trap and solid-phase micro-extraction (SPME).

Experiment 2. Develop validated method for the qualitative assessment of electronic cigarettes artifacts using Direct Analysis in Real Time Accu-TOF™ Mass Spectrometry (DART). A quantitative method will also be assessed.

Goal: To develop a simple trap to analyze the aerosol from e-cigarettes.

Results: A simple trap was developed and validated to analyze aerosol via SPME and to trap ingredients/drugs in water. Erlenmeyer flasks were connected to a vacuum with tubing and glass wool filters in between for capture. Corks were drilled to accommodate the tubing attached to the e-cigarette and a septum for the SPME sampling (Figure 1). Briefly, two Erlenmeyer flasks were connected in tandem to a vacuum with a flow rate of 2.3 L/min. DI-water was added to each trap and a gas dispersion tube bubbled the aerosol into the water. Glass wool was placed in between the two traps to contain the aerosol in the first trap. Results are reported in Aim 2.

Goal: To develop a sampling protocol in order to use solid-phase microextraction (SPME) to capture aerosol produced by an e-cigarette for analysis by a SPME GC-MS and SPME-DARTMS methods in order to both qualitatively and quantitatively assess the amount of nicotine and flavoring agents found in e-cigarette aerosol.

Results: Polydimethylsiloxane (PDMS) SPME fibers were demonstrated to successfully capture nicotine and flavoring agents in concentrations that were analyzed by GC-MS and DART-MS. The aerosol produced by the e-cigarette was trapped with the apparatus described above. A 7µm or 10 µm PDMS SPME fiber was inserted through a stopper in the first trap, depending on the molecular weight of the drug. The fiber was introduced into the trap while the e-cigarette was activated for four seconds, aerosolizing 7-10 µL and the aerosol filled the trap. The SPME fiber was held in the trap for five minutes, after which the fiber was removed.

The SPME fiber was then inserted into the injection port of an Agilent GC-MS 6890N/5973 Mass Selective Detector with an HP-5MS column 30 m × 0.25 mm id × 0.25 µm. The injection port was set to 315°C and the run was made in splitless mode with a 15-minute thermal desorption time. The initial temperature was set to 120°C, with a ramp to 300°C at 10°C/min, with a hold time of 12 min at 300°C, for a total run time of 30 min. The fibers were thermally cleaned between runs to ensure no carryover occurred between samples. (Figure 2).

Alternatively, the SPME fiber was waved in the helium stream of the DART-MS following previously validated methods. The analysis was performed in positive-ion mode with a helium stream temperature of 300°C. The ion guide peak voltage was 400 V, reflectron voltage was 900 V, orifice 2 was set to 5 V, and the ring lens was set to 3 V with orifice 1

operated in function switching mode at 20, 60, or 90 V with a single data file created for all three voltages. The range of masses measured was from 40 to 1100 Da. (Figure 3).

The general analytical scheme adopted in the laboratory was that all e-liquids were screened by DART-MS. Samples were then quantitated by GC-MS or LC-MS/MS. Samples were aerosolized and active ingredients were extracted by SPME for analysis by DART-MS and GC-MS in order to demonstrate that pharmacologically active ingredients were in the vapor. See Figure 4 for examples.

Experiment 3. Quantify nicotine and adulterant pharmaceuticals by LCMS³.

Goal: Validated method for nicotine and Drugs Other Than Nicotine (DOTNs) by LCMS³.

Results: The nicotine concentrations of the e-liquids were determined using HPLC-MS/MS with a Hypersil® Gold 3x50 mm, 5 μ m column and a method previously published. The mobile phase consisted of 1:9 DI water with 10 mmol ammonium acetate and 0.1% formic acid: methanol, and was run at an isocratic flow rate of 0.5 mL/min. The injection volume was 10 μ L. The ion spray voltage was 5000 V and the source temperature was 600°C with 30 mL/min curtain gas flow. The instrument was operated in multiple reaction monitoring mode (MRM) monitoring the following m/z transitions: nicotine, 163 > 130 and 163 > 117; and nicotine-d4, 167 > 134. A linear regression was plotted of peak area ratio of nicotine to internal standard versus nicotine concentration.

A method for quantitation of methamphetamine was validated using an Agilent 6890N Gas Chromatograph coupled to a 5973 Mass Selective Detector per SWGTOX guidelines. Chromatographic separation was performed on a HP-5MS column 30 m x 0.25 mm id x 0.25 mm (Agilent, Santa Clara, CA). The GC/MS was operated in a split mode at a ratio of 6:1, with 1 μ L injection volume. The carrier gas was helium at a linear velocity of 35 cm/s. The GC had an oven temperature of 120°C-200°C at a rate of 10°C/min then ramped to 280°C at a rate of 30°C/min. The MSD was operated in SIM mode with 58, 64, 91, 96, 134 m/z as the selected ions. Quantification was performed using 58 and 64 m/z as the quantitative ions for methamphetamine and methamphetamine-d11, respectively. The qualitative ions for methamphetamine were 91 and 64 m/z and 91 m/z for methamphetamine-d11. The total run time of 10.67 minutes. A six-point calibration curve was constructed with methamphetamine concentrations of 100, 200, 500, 750, 1000, and 2000 ng/mL with 500 ng/mL of methamphetamine-d11 as internal standard. The calibration curve was matrix-matched and was extracted from water using the method previously described. A linear regression was generated using the peak area ratio counts of methamphetamine and internal standard versus the theoretical calibrator concentrations, and $r^2 > 0.9981$ for all curves. The limit of quantitation was administratively set to 100 ng/mL. Six sets of controls were included with each analytical batch: Limit of Detection QC (100 ng/mL), Low QC (150 ng/mL), Mid QC (600 ng/mL), High QC (1500 ng/mL), a blank, and a double blank. Intraday precision and bias were determined by the largest percent coefficient of variation (% CV) and by the largest percent difference of the five runs (N = 5). Carryover was assessed by injecting the lowest quality control (150 ng/mL) following the injection of the high-quality control (1500 ng/mL). (Figure 5).

A method for the quantitation of methadone was validated using an Agilent 6890N Gas Chromatograph coupled to a 5973 Mass Selective Detector per SWGTOX guidelines.

Chromatographic separation was performed on a HP-5MS column 30 m x 0.25 mm id x 0.25 mm (Agilent, Santa Clara, CA). The GC/MS was operated in a split mode at a ratio of 20:1, with 1 μ L injection volume. The carrier gas was helium at a linear velocity of 20 mL/min. The GC had a front inlet temperature of 275°C. The temperature program began with the oven temperature of 225°C, and then programmed at a rate of 15°C/min to 285°C. The MSD was operated in SIM mode with 72, 223, 294, and 309 m/z as the selected ions for methadone and 78, 226, 303, and 318 m/z for methadone-d9. A seven-point calibration curve ranging from 100-5000 ng/mL of methadone was prepared along with a blank, a double blank control, and controls containing methadone and its internal standard were analyzed. The controls were run in triplicate with Limit of Detection/Quantitation control at 100 ng/mL; a low-control at 150 ng/mL; a mid-control at 1000 ng/mL; and a high-control at 4500 ng/mL. The limit of detection was arbitrarily set to match the limit of quantitation at 100 ng/mL. An internal standard (500 ng/mL methadone-d9) was added to each calibrator, blank, controls, and sample. The coefficient of determination (r^2) was $\geq$ 0.9985 for all calibration curves. The bias for all the controls ($n = 3$) for methadone ranged from 5-15% with coefficient of variance (% CV) of 20%. Carryover was assessed by injecting the lowest quality control following the injection of the high-quality control.

Experiment 4. Develop a dynamic headspace GCMS (DHS GCMS) method for the direct analysis of e-cigarette components.

Challenge: The DHS GC-MS had significant equipment failures over many months. A method for headspace analysis used in the analysis of fire debris evidence was concept tested to analyze atomizers on e-cigarettes. It was demonstrated that this method could be adopted for nicotine analysis. However, this method did not work for the analysis of methamphetamine. Static headspace with the charcoal strip used in nicotine analysis was evaluated a number of times with a number of extraction time periods and temperature parameters for methamphetamine analysis. Methamphetamine was demonstrated to aerosolize; however, it was not extracted from the aerosol onto the charcoal test strip or it was not possible to extract it from the charcoal test strip. The conclusion is that the charcoal test strip was not suitable for some drugs.

Aim 2

Characterize representative electronic cigarettes available for consumers to purchase, to include efficacy of drug delivery.

Experiment 1. Characterize major classes of e-cigarette devices available for consumers to purchase and describe the function of each component.

Goal: The three major types of e-cigarettes were characterized (Figure 6-9). In order to understand the relationship between voltage, resistance, heat, and concentration of drugs in the aerosol, coil temperatures were assessed at various voltages and various gauges.

Method: Two popular types of wire used within the e-cigarette community are Kanthal A-1 and Nichrome 80:20. Coils can be either contact or non-contact. Contact coils are tightly wrapped and the wire touches each wrap. Non-contact coils do not touch and typically have the wraps evenly spaced apart from one another. The temperature of the coils for the dry burns and wet burns when the coil is wrapped to the same resistance and burned at the same voltages were assessed. Both metal types will be evaluated at the same resistance ($1.8\ \Omega$), wet and dry, contact and non-contact, with wire gauge ranging from 26 to 36 and at 3.5, 3.7, 4.2, 4.5, 5.0, 5.5, and 6.0 volts, with replicates of at least 3 for each variable. The atomizer was a Kayfun Lite Close Atomizer. The type of atomizer is less important than the assessment of the coils as the atomizer was attached to a constant power supply instead of a battery. Center coil temperatures of two wire types, each in three gauges, wrapped in both contact and non-contact, fired at four voltages, and wet with 100% VG or kept dry were measured. All coils were hand-built to $1.8\ \Omega$ resistance. Temperatures were measured using a Micro-Epsilon IR sensor with a laser sighting.

To complicate this single coil model, users have begun to use dual coils in parallel for a technique called “sub-ohming” ($<1\ \Omega$). As opposed to a single coil being wrapped to a resistance of $1.8\ \Omega$, 2 coils are each wrapped to about $1.2\ \Omega$ and are aligned in parallel to create a resistance of $0.6\ \Omega$ (Figure 10). In order to explore if there was potentially a significant difference between the 2 types of atomizers, a short study was conducted.

Results: In the dry configuration, Kanthal is the hotter wire, meaning it is able to sustain hotter temperatures. This is not surprising since it is an alloy composed of iron, chromium, and aluminum and has a melting point of 1400°C . Nichrome is a nickel and chromium alloy with a melting point of 1200°C . Not surprisingly, contact is hotter than non-contact.

When coils had a wick wet with 100% vegetable glycerin (VG), no statistically significant difference was seen between wire gauge, wire type, and wire configuration. Hence, VG is a limiting factor to coil temperature (Figures 11-12).

These findings are significant because they provide some basis for understanding the vaporization of drugs into the aerosols. More importantly, the temperature of the wet coils disproves user claims that the wet coils get hotter with Kanthal. The real value of using Kanthal is that the melting temperature is higher for those who are vaping off dry coils. While temperature may be the same, it is unknown as to if the wire type and size may be impacting the particle size of the aerosols.

When the coils are in contact with 100% propylene glycol (PG), the temperature output between the two mediums differed significantly. The PG medium had lower temperature outputs than VG, reaching temperatures as low as 160°C and as high as 360°C . The type of coil, Kanthal A-1 or nichrome 80:20 did not have a significant difference in temperature nor did differing coil configurations. There was a trend of temperature increase with decreasing wire thickness. These results contradict what most e-cigarettes users claim: That wire type and configuration have an impact on the temperature outputs of the coils and how they vaporize the e-liquid. It appears that the medium that the coils are submerged in have a more significant impact in the temperature outputs of the coils, which may also lead to an impact in the particle size produced.

The temperature profile of the dual dry 26 gauge Kanthal coils wrapped in contact from 3.5 to 5.0 V showed minor temperature variations between the two coils. This is predominantly due to the nature of how much wire is touching the contacts. Microns of metal length can impact resistance enough to change the temperature profile between the two coils

in the same atomizer. The temperature profile for the 26 gauge Kanthal dual coil sub-Ohm at 3.7 V is significantly higher than what was found with the 26 gauge Kanthal single coil 1.8 Ω at 3.7 V wire (951°C and 793°C, respectively), both wrapped in contact and dry, due to the difference between resistances of the coils. By holding the voltage constant between the two e-cigarette models, the current running through the lower resistance dual coil model is higher, leading to higher wattage and higher temperatures.

Experiment 2. Characterize the delivery of nicotine in e-cigarettes, based upon device type and voltage, in terms of concentration of nicotine in the liquid and concentration of nicotine in the vapor. After this is characterized, adulterant illicit drugs will also be evaluated (THC, methamphetamine, opiates, and other drugs as necessary and time permits).

Goal: Characterize the concentration of nicotine in aerosol based on the performance of the device, including varying the voltage to manipulate the heat produced by the heating element.

Results: Studies showed that the yield of nicotine in the aerosolized e-liquid consisting of 50:50 propylene glycol:vegetable glycerin (PG:VG) with 12 mg/L nicotine (delivered by a KangerTech AeroTank, 1.8 Ω preassembled atomizer with eGo-V2 variable voltage battery e-cigarette, Nichrome, 34 gauge, non-contact coil) increased with increasing voltage (3.9, 4.3, and 4.7 V), from 89 μg to 125 μg (based on weight difference of the tank) (see figure). The concentration of nicotine recovered from the traps, as determined by LC-MS³, averaged 378 ng/ml (+/- 64). As seen with the nicotine yield, the aerosol concentration increased from 322 to 374 to 432 ng/ml, at 3.9, 4.3, and 4.7 V, but had moderately high SD. The average recovery of nicotine in the trap across the voltages was 101%, ranging from 82-113% (Figure 13).

See Aim 1 for analysis of methamphetamine in e-liquids. A study was conducted to determine if increasing voltage of the e-cigarette yielded higher dosing in the aerosol. The study concluded that there was no significant difference in the concentration of methamphetamine as the voltage of the e-cigarette increased, serving to contradict the users' myth. Three concentrations of methamphetamine were prepared in 50:50 PG:VG (v:v) and aerosolized at 3.9, 4.3, and 4.7 V for 4 seconds at 2.3 ml/minute. Five replicates were analyzed at each voltage. The change in voltage did not significantly alter the dose of methamphetamine contained in the aerosol (Figure 14).

For methadone, the theoretical dose capture concentrations were determined from the gravimetric difference of the e-cigarette tank before and after aerosolization into the trap. At 10 mg/mL of methadone in the e-liquid, the dose per puff was expected to from 38 to 46 μg with increasing voltage. For the 30 mg/mL e-liquid, the predicted concentrations ranged from 170 to 221 μg and the 60 mg/mL e-liquid from 234 to 549 μg . GC/MS results showed that at 10 mg/mL, the average dose per puff at 3.9 and 4.7 V was 8 and 4 μg respectively with a 19 and 8% recovery. At 30 mg/mL the average doses were 37 and 17 μg with 16 and 10% recovery, and at 60 mg/mL, the average doses were 30 and 417 μg with 12 and 79% recovery. Statistical analysis of ANOVAs comparing the dose capture results by voltage showed that there was not a difference between the dosage at 3.9 and 4.3 V ($P = 0.76$), but that there was a difference in the dosage between 3.9 and 4.7 V and 4.3 and 4.7 V ($P < 0.001$). The hypothesis regarding the low recovery of methadone from the aerosol is that the boiling point for methadone is higher than the temperature of the coil in the electronic cigarette.

Experiment 3. Characterize the formation of potential biomarkers formed during pyrolysis based on the wattage of the e-cigarette.

Goal: Characterization of coil temperature studies have revealed that the coils, after multiple burns begin to deteriorate. A study to characterize the degradation of the coils by SEM-EDX was conducted.

Results: Nichrome and Kanthal wires at 30, 32, and 34 gauges were triggered 1, 50, and 150 times in both contact, and non-contact coil configurations. The voltage used was dependent on the gauge and coil configuration and can be found in Table 1. All coils were triggered dry for 10 seconds, and SEX-EDX analysis was completed at 2000x magnification. Two metals for each wire type showed a significant decrease at 1, 50, and 150 burns as compared to a pristine (unburned) coil. Kanthal wires showed a significant decrease in iron and chromium, while nichrome wires showed a significant decrease in iron and nickel. Statistical analysis shows that there is no significant difference in iron or nickel loss between gauges for nichrome wires, while Kanthal wires were found to have significantly less loss of iron and chromium with 30 gauge wire as compared to 32 and 34 gauge wire. The data also suggests that Kanthal coils wrapped in a contact configuration lead to a significantly higher loss of iron and chromium when compared to the non-contact configuration. Nichrome wires, however, show a general trend of no difference in nickel and iron loss when comparing final metal percentage of contact and non-contact configurations. Overall, the data has shown that the metal composition of both nichrome and Kanthal wires decreases significantly after 1 burn and progressively deteriorates as the number of burns increases. This effect is independent of wire type, gauge, and configuration (Figures 15-17).

A method is being validated on the Agilent 7700 ICP-Mass Spectrometer to analyze metals in the aerosol. A filter system had to be developed to capture the aerosol. Using the e-cigarette system as previously described, ten 30 gauge Kanthal and Nichrome wires were heated for 10 seconds and the aerosol was each trapped onto a single 0.1 micron Teflon hydrophobic filter. This was repeated 10 times. They were digested in aqua regia, diluted, and analyzed by ICP-MS. Samples were run to eliminate the potential that metal would be in the aerosol from the wick, PG, and VG. Preliminary data demonstrates that the metal is contained in the aerosol and does not condense in the mouthpiece of the atomizer. Average ppb of chromium-53, iron-57, and nickel-60 for Kanthal was 11.0 (± 15.4), 41.9 (± 58.7), and 4.04 (± 5.60), respectively.

Aim 3

Characterize the liquid refill products for electronic cigarettes, to include nicotine and adulterant pharmaceuticals.

Experiment 1. Characterize variation in supplies purchased by consumers:

Goal: Characterize the e-liquids for e-cigarettes, to include nicotine and adulterant pharmaceuticals (THC, methamphetamine, heroin).

Results: A stability study was conducted to understand the quality of e-liquids and how they might impact nicotine concentration. Samples were stored in three types of containers in three conditions: 24 hours light at room temperature (RT), 24 hours dark at room temperature, and 24 hours dark at 40 °C. They were samples periodically and analyzed by LC-MS/MS. The concentration of nicotine decreased significantly from time 0 through time 12 weeks, and then plateaued for the remaining time when exposed to light conditions. For example, the 36 mg/mL sample kept in 24 hour light at room temperature decreased to 27.8 mg/mL in 12 weeks. The container type (glass, plastic, and amber glass) did not impact the concentration of nicotine in the sample. The concentration of nicotine in commercial samples deteriorated from 20.5 mg/mL to 13.2 mg/mL in 12 weeks and then plateaued. However, no statistically significant difference exists between light and RT, dark and RT, and dark and refrigerated (Figure 18).

Goal: Characterize e-liquids purchased online for “truth in advertising”

Results: Nicotine concentrations of 27 commercial e-liquids were compared to advertised nicotine concentration (Table 1). Actual concentrations varied 53-139% from advertised. Glycol ratios in the 27 commercial e-liquids were compared to advertised label concentration and found to be in general agreement.

A sample of e-liquid was received in the laboratory labeled as a cannabinoid-based products. The concentrations of the THC, 42.6% (v:v), and CBD, 0.5% (v:v), were different then the labeled content, THC at 69% and CBD at 1%. Four additional unlabeled cannabinoids were identified and quantitated. Fourteen terpene compounds were identified: α -pinene, 3-myrcene, 3-pinene, limonene, (1R)-endo-(+)-fenchyl alcohol, linalool, α -terpineol, 3-caryophyllene, α -humulene, cis/trans nerolidol, guaiol, (+)-cedrol, and α -bisabolol. The identification of these unlabeled cannabinoids and marijuana terpenes indicated the e-liquid was produced by extraction of marijuana.

Cannabidiol (CBD) was listed as the active ingredient in e-liquids found online. Two e-liquids were acquired that claim to be infused with CBD and contained 3.3 mg/mL CBD. They screened positive by DART-MS and CBD was quantitated by LC-MS³ at 6.53 and 7.61 mg/mL. The website (cloud9hemp.com) has an FDA Disclosure statement that reads “... FDA considers non-THC based hemp products to be “food based” and therefore legal...CBD Rich Hemp Oil is legal in all 50 states.” They also state that the products are “not intended to diagnose, treat, or cure any disease.”

Ethanol was determined in 53 of the 56 e-liquids by HS GC-FID. Only one e-liquid included ethanol as a labeled component. Thirty of 42 e-liquid samples were reported as positive for ethanol with concentrations > 3.70 g/mL. Once it was determined that commercial e-liquids contain ethanol, coil temperatures were evaluated for any significant change from the original temperature studies conducted without ethanol in lab-prepared e-liquids. Temperatures were significantly lower in some cases and higher in others. Therefore, it could be said that the temperature the coils were unpredictable with ethanol in the e-liquid (Figure 19).

PROJECT FINDINGS

Aim 1

Develop reliable, validated analytical methods to support the efficient and thorough analysis of e-cigarette devices, device components, and aerosol for pharmaceuticals in adulterated, unadulterated, and self-prepared formulations.

1. DART-MS, LC-MS³, and GC-MS methods were successfully validated to screen, confirm, and quantitate pharmacologically active ingredients in e-liquids and the aerosol.
 - a. A trap and SPME extraction method were developed and validated to successfully capture the aerosol produced by an e-cigarette.

Aim 2

Characterize representative electronic cigarettes available for consumers to purchase, to include efficacy of drug delivery.

1. Increases in voltage do not increase the temperature of the coil significantly and do not yield significantly higher concentrations of the pharmacologically active ingredient (nicotine or methamphetamine) in the aerosol.
2. Metal composition of both nichrome and Kanthal wires decreases significantly after 1 burn and progressively deteriorates as the number of burns increases. This effect is independent of wire type, gauge, and configuration.

Aim 3

Characterize the liquid refill products for electronic cigarettes, to include nicotine and adulterant pharmaceuticals.

1. Given that the e-cigarette industry is un-regulated, it should not be unexpected to find nicotine or glycol concentrations different than the labeled concentrations on e-cigarette liquid formulations.
2. Poor QA/QC in facilities producing e-liquid products result in products that have significantly less or significantly more than what is indicated on the bottle.
3. Some e-liquids are not labeled as to the pharmacologically active component, nor are they advertised by the vendor. Indicators that a product contains a DOTN is that it is 2-10 times more expensive than a nicotine-based e-liquid.
4. Ethanol was a major component in most e-liquids and was only labeled in one product.

FUTURE STUDIES

1. It is imperative to evaluate how vaping alcohol impacts field sobriety tests and BAC.
2. It is important to continue to monitor how the technology for e cigs continues to evolve. In the 2.5 years of this study, the types of e cigarettes have grown significantly in order to vape dry herb, waxes, dabs, oils, and other types of tinctures.
3. Eutectic mixtures should be explored to assess improving the aerosolization of high molecule weight molecules, such as opioids, particularly since user blogs indicate recommendations for cutting these drugs with caffeine before putting into e liquids.

DISSEMINATION/PRODUCTS/ACCOMPLISHMENTS

This research group has aggressively presented and published its finding. Twenty scientific presentations have been made (Table 2). Two traditional workshops and two webinars were conducted. Six peer-reviewed manuscripts have been published, and three more are in preparation and on-track for submission by June.

Findings from this study were also disseminated in China, but NIJ provided no funding for this travel.

Chapter 362

OUTBREAK OF LUNG INJURY ASSOCIATED WITH E-CIGARETTE USE, OR VAPING

Centers for Disease Control and Prevention

Posted October 3, 2019 at 4:00pm ET

CDC, the U.S. Food and Drug Administration (FDA), state and local health departments, and other clinical and public health partners are investigating a multistate outbreak of lung injury associated with use of e-cigarette, or vaping, products.

WHAT WE KNOW

- As of October 1, 2019, 1,080* lung injury cases associated with using e-cigarette, or vaping, products have been reported to CDC from 48 states and 1 U.S. territory.
- Eighteen deaths have been confirmed in 15 states.
- All patients have reported a history of using e-cigarette, or vaping, products.
- Most patients report a history of using THC-containing products. The latest national and regional findings suggest products containing THC play a role in the outbreak.
- Approximately 70% of patients are male.
- Approximately 80% of patients are under 35 years old.
 - 16% of patients are under 18 years old
 - 21% of patients are 18 to 20 years old

WHAT WE DON'T KNOW

- The specific chemical exposure(s) causing lung injuries associated with e-cigarette use, or vaping, remains unknown at this time.
- No single product or substance has been linked to all lung injury cases.

- The outbreak is occurring in the context of a dynamic marketplace for e-cigarette, or vaping, products, which may have a mix of ingredients, complex packaging and supply chains, and include potentially illicit substances.
- Users may not know what is in their e-cigarette or e-liquid solutions. Many of the products and substances can be modified by suppliers or users. They can be obtained from stores, online retailers, from informal sources (e.g. friends, family members), or “off the street.”
- More information is needed to know whether one or more e-cigarette or vaping products, substances, or brands is responsible for the outbreak.

WHAT CDC RECOMMENDS

- While this investigation is ongoing, CDC recommends that you consider refraining from using e-cigarette, or vaping, products, particularly those containing THC.
- If you are an adult who used e-cigarettes containing nicotine to quit cigarette smoking, do not return to smoking cigarettes.
- If you have recently used an e-cigarette or vaping product and you have symptoms like those reported in this outbreak, see a healthcare provider.
- Regardless of the ongoing investigation:
 - Anyone who uses e-cigarette, or vaping, products should not buy these products (e.g., e-cigarette or vaping products with THC or CBD oils) from informal sources (e.g. friends, family members) or “off the street,” and should not modify or add any substances to these products that are not intended by the manufacturer.
 - Youth and young adults should not use e-cigarette, or vaping, products.
 - Women who are pregnant should not use e-cigarette, or vaping, products.
 - Adults who do not currently use tobacco products should not start using e-cigarette, or vaping, products.
 - THC use has been associated with a wide range of health effects, particularly with prolonged heavy use. The best way to avoid potentially harmful effects is to not use THC, including through e-cigarette, or vaping, products. Persons with marijuana use disorder should seek evidence-based treatment by a health care provider.

KEY FACTS ABOUT E-CIGARETTE USE, OR VAPING

- Electronic cigarettes – or e-cigarettes — are also called vapes, e-hookahs, vape pens, tank systems, mods, and electronic nicotine delivery systems (ENDS).
- Using an e-cigarette product is commonly called vaping.
- E-cigarettes work by heating a liquid to produce an aerosol that users inhale into their lungs.
- The liquid can contain: nicotine, tetrahydrocannabinol (THC) and cannabinoid (CBD) oils, and other substances and additives. THC is the psychoactive mind-altering compound of marijuana that produces the “high”.

LATEST OUTBREAK INFORMATION

- As of October 1, 2019, 1,080 lung injury cases associated with the use of e-cigarette, or vaping, products have been reported to CDC from the following states and 1 U.S. territory: AL, AR, AZ, CA, CO, CT, DE, FL, GA, HI, IA, ID, IL, IN, KS, KY, LA, MA, ME, MD, MI, MN, MO, MT, MS, NC, ND, NE, NJ, NM, NV, NY, OH, OK, OR, PA, RI, SC, SD, TN, TX, UT, VA, VT, WA, WI, WV, WY, and USVI.
- Eighteen deaths have been confirmed in 15 states: Alabama, California (2), Delaware, Florida, Georgia, Illinois, Indiana, Kansas (2), Minnesota, Mississippi, Missouri, Nebraska, New Jersey, Oregon (2), and Virginia. More deaths are under investigation.
 - The median age of deceased patients was 49.5 years and ranged from 27-71 years.
- Among 889 patients with data on age and sex:
 - 70% of patients are male.
 - The median age of patients is 23 years and ranges from 13-75 years.
 - 81% of patients are under 35 years old.
 - By age group category:
 - 16% of patients are under 18 years old;
 - 21% of patients are 18 to 20 years old;
 - 18% of patients are 21 to 24 years old;
 - 26% of patients are 25 to 34 years old; and
 - 19% of patients are 35 years or older.
- The latest findings from the investigation into lung injuries associated with e-cigarette use, or vaping, suggest products containing THC play a role in the outbreak.
- All patients have a reported history of e-cigarette product use, or vaping, and no consistent evidence of an infectious cause has been discovered. Therefore, the suspected cause is a chemical exposure.
- The specific chemical exposure(s) causing lung injuries associated with e-cigarette product use, or vaping, remains unknown at this time.
- No single product or substance has been linked to all lung injury cases. More information is needed to know whether a single product, substance, brand, or method of use is responsible for the outbreak.
- Among 578 patients with information on substances used in e-cigarette, or vaping, products in the 3 months prior to symptom onset:
 - About 78% reported using THC-containing products; 37% reported exclusive use of THC-containing products.
 - About 58% reported using nicotine-containing products; 17% reported exclusive use of nicotine-containing products.
- This complex investigation spans many states, involves hundreds of patients, and involves a wide variety of substances and e-cigarette, or vaping, products.

WHAT CDC IS DOING

- CDC is working 24/7 to identify the cause or causes of this outbreak through partnerships with states and other federal agencies.
- CDC has activated the Emergency Operations Center (EOC) to coordinate activities and provide assistance to states, public health partners and clinicians around the nation.
- CDC's Lung Injury response efforts are committed to:
 - Identify and define the risk factors and the source for lung disease associated with e-cigarette product use, or vaping.
 - Detect and track confirmed and probable cases in the US.
 - Communicate actionable recommendations to state, local, and clinical audiences.
 - Establish lab procedures that can assist with the public health investigation and patient care.
- CDC continues to work closely with FDA, states, public health partners, and clinicians on this investigation by providing consultation and technical assistance to states on communication, health alerts, public outreach, and surveillance.
- CDC is maintaining an outbreak webpage with key messages and weekly updates on case counts, deaths, and resources.
- CDC is holding congressional briefings, media telebriefings, and regular calls with health departments, clinicians to provide timely updates.
- CDC worked with states to create a case definition to classify confirmed and probable cases in a consistent way. States are in the process of classifying patients. We expect that states and clinicians may look back for past lung injury cases based on CDC's case definition CDC will report numbers of confirmed and probable lung injury cases once states have finalized their classification of cases.
- By invitation, CDC has deployed Epidemic Intelligence Service (EIS) officers to states to conduct Epi-Aids.
- CDC has started collecting and testing clinical lab specimens to learn more about this lung injury.
- CDC developed guidance documents for were created to assist public health laboratories, healthcare providers, and pathologists, and others, with specimen collection, storage, and submission.

FOR THE PUBLIC: WHAT YOU NEED TO KNOW

Symptoms of Lung Injury Reported by Some Patients in This Outbreak

- Patients in this investigation have reported symptoms such as:
 - cough, shortness of breath, or chest pain
 - nausea, vomiting, or diarrhea
 - fatigue, fever, or abdominal pain

- Some patients have reported that their symptoms developed over a few days, while others have reported that their symptoms developed over several weeks. A lung infection does not appear to be causing the symptoms.

Figure 1. Dates of symptom onset and hospital admission for patients with lung injury associated with e-cigarette use, or vaping — United States, March 31–September 28, 2019.

Recommendations

You should consider refraining from using e-cigarette, or vaping, products, particularly those containing THC.

If you have recently used an e-cigarette, or vaping, product and you have symptoms like those reported in this outbreak, see a healthcare provider.

If you use e-cigarette, or vaping, products, you should:

- Not buy these products (e.g., e-cigarette or vaping products with THC or CBD oils) off the street, and not modify or add any substances to these products that are not intended by the manufacturer.
- See a healthcare provider right away if you have symptoms like those reported in this outbreak.

If you are an adult who uses e-cigarettes because you have quit cigarette smoking:

- Do not return to smoking cigarettes.
- If you continue to use e-cigarettes, carefully monitor yourself for symptoms and see a healthcare provider right away if you have symptoms like those reported in this outbreak.

If you are an adult who is trying to quit smoking:

- Contact your healthcare provider if you need help quitting tobacco products, including e-cigarettes.

- Use evidence-based treatments, including counseling and FDA-approved medication[external icon](#).

If you are an adult who is addicted to marijuana:

- Effective treatments are available and recovery is possible.
- A number of therapy-based treatments such as cognitive-behavioral therapy, contingency management, motivational enhancement therapy, and multi-dimensional family therapy have been shown to help people who are addicted to marijuana.
- Visit the Substance Abuse and Mental Health Services Administration's treatment locator[external icon](#) to find treatment in your area, or call 1-800-662-HELP (4357).

If you are a teen or young adult who is trying to quit nicotine or marijuana:

- Visit the Substance Abuse and Mental Health Services Administration's treatment locator[external icon](#) to locate treatment in your area, or call 1-800-662-HELP (4357).
- Visit the National Institute on Drug Abuse for Teens' What to Do If You Have a Problem with Drugs: For Teens and Young Adults[external icon](#).
- Get resources and support at Smokefree Teen[external icon](#) and Truth Initiative[external icon](#).

If you are concerned about your health after using an e-cigarette, or vaping, product, contact your health care provider, or you can also call your local poison control center at 1-800-222-1222.

Regardless of this investigation, CDC recommends:

- Youth and young adults should not use e-cigarette, or vaping, products.
- Women who are pregnant should not use e-cigarette, or vaping, products.
- Adults who do not currently use tobacco products should not start using e-cigarette, or vaping, products.
- THC use has been associated with a wide range of health effects, particularly with prolonged heavy use. The best way to avoid potentially harmful effects is to not use THC, including through e-cigarette, or vaping, products. Persons with marijuana use disorder should seek evidence-based treatment by a health care provider.

QUESTIONS ABOUT E-CIGARETTE USE, OR VAPING

What Is an E-Cigarette?

- Electronic cigarettes – or e-cigarettes – work by heating a liquid to produce an aerosol that users inhale into their lungs.
- The liquid can contain: nicotine, tetrahydrocannabinol (THC) and cannabinoid (CBD) oils, and other substances, flavorings, and additives.

- E-cigarettes are also called vapes, e-hookahs, vape pens, tank systems, mods, and electronic nicotine delivery systems (ENDS).

What Is Vaping?

- Using an e-cigarette is commonly called vaping.
- Vaping can refer to using e-cigarettes to inhale many substances, including nicotine, and THC or CBD oils.

What Is Causing This Outbreak of Lung Injury?

- The specific chemical exposure(s) causing lung injuries associated with e-cigarette use, or vaping, remains unknown at this time.
- No single product or substance has been linked to all lung injury cases. The outbreak is occurring in the context of a dynamic marketplace for e-cigarette or vaping products, which may have a mix of ingredients, complex packaging and supply chains, and include potentially illicit substances. Users may not know what is in their e-cigarette or e-liquid solutions. Many of the products and substances can be modified by suppliers or users. They can be obtained from stores, online retailers, from informal sources (e.g. friends, family members), or “off the street.”
- More information is needed to know whether one or more e-cigarette or vaping products, substances, or brand is responsible for the outbreak.

How Can I Protect Myself?

- While this investigation is ongoing, CDC recommends that you consider refraining from using e-cigarette, or vaping, products, particularly those containing THC.
- Anyone who uses an e-cigarette or vaping product should not buy these products (e.g., e-cigarette or vaping products with THC or CBD oils) off the street, and should not modify or add any substances to these products that are not intended by the manufacturer.
- If you are an adult who uses e-cigarettes because you have quit cigarette smoking, you should not return to smoking cigarettes.

What Should I Do If I Have Used E-Cigarettes and Have Symptoms?

- See a healthcare provider right away if you have symptoms like those reported in this outbreak.
- You can also call your local poison control center at 1-800-222-1222.

- You can also submit a detailed report of any unexpected health or product issues related to tobacco or e-cigarette products to the FDA via the online Safety Reporting Portal [external icon](#).

What If I'm an Adult Who Quit Cigarette Smoking and Now Uses E-Cigarettes?

- If you are an adult who uses e-cigarettes because you have quit cigarette smoking, do not return to smoking cigarettes.
- If you continue to use e-cigarettes, carefully monitor yourself for symptoms and see a healthcare provider right away if you have symptoms like those reported in this outbreak.

What Is Marijuana (THC)?

- Marijuana, which can also be called weed, pot, dope, or cannabis, is the dried flowers and leaves of the cannabis plant.
- Marijuana contains mind-altering (e.g., psychoactive) compounds like tetrahydrocannabinol, or THC, as well as other active compounds like cannabidiol, or CBD, that are not mind-altering.
- For more information visit the CDC web page [Marijuana and Public Health](#)

What Are the Health Risks of Marijuana (THC)?

- Marijuana use has been associated with a wide range of health effects, particularly with prolonged heavy use.
- These effects range from short-term problems with attention, memory, learning, to longer-term problems such as psychosis, anxiety, suicidal ideation and attempts, depression, and substance use disorder. It is not known whether these are causal relationships or simply associations.
- The best way to avoid potentially harmful effects is to not use marijuana.

How Does Marijuana Use during Adolescence Affect Youth?

- Marijuana use, including in e-cigarettes or through vaping, is associated with a broad range of health effects. Marijuana use can harm the developing adolescent brain and impact attention, learning, and memory. Starting to use marijuana at a younger age increases the likelihood of frequent and problematic use later in life.
- Youth marijuana use has also been associated with antisocial and oppositional behaviors, nicotine use, poor school performance, use of other illicit substances and

the development of substance use disorders, and impairments in social relationships. See the recent Surgeon General's Advisory: Marijuana Use and the Developing Brain [external icon](#).

- Regardless of the substance used, e-cigarette or vaping products should never be used by youth or pregnant women. It is important for parents to communicate with their child about the risks of nicotine, THC, or other substance use. CDC offers a [Talk With Your Teen About E-cigarettespdf iconexternal icon](#) tip sheet to help parents talk with their children about why e-cigarettes are harmful for them.

What Should I Do if I Am Currently Vaping Marijuana/THC for Medical Use?

- While this investigation is ongoing, CDC recommends that persons consider refraining from using e-cigarette or vaping products, particularly those containing THC. Until we have more information, this includes THC-containing products obtained from any source but in particular, individuals should not purchase from informal sources (e.g. friends, family members), or “off the street.”
- If you have recently used a THC-containing product in an e-cigarette or vaping product and you have symptoms like those reported in this outbreak see a healthcare provider.
- We do not know if there are different health effects of using different forms of marijuana, such as smoking, vaping, and edibles, to recommend transitioning from one mode of use to another to reduce harm. Talk with your healthcare provider about other available treatment options for the conditions).

How Are States Regulating THC-Containing Vaping Products?

- Some states have legalized the use of THC-containing vaping products for nonmedical and/or medical purposes.
- State regulations vary with regard to product pre-approval processes, ingredient requirements and/or limitations, packaging and labeling, and testing requirements and methods. States typically conduct various levels of testing of products, including testing for potency, contaminants, metals, pesticides, and/or pathogens.
- Both THC-containing and nicotine-containing e-cigarette, or vaping, products purchased legally within states might also contain harmful substances. It is difficult to know what is in these products, and full ingredient lists are typically not available. It is difficult to know what substances the products contain and potential for harm.

RECOMMENDATIONS FOR CLINICIANS

1. Report cases of lung injury of unclear etiology and a history of e-cigarette or vaping product use within the past 90 days to your state or local health department.

Reporting of lung injury cases may help CDC and state health departments determine the cause of these lung injuries.

2. Ask all patients who report e-cigarette, or vaping, product use within the last 90 days about signs and symptoms of respiratory illness.
3. If e-cigarette, or vaping, product use is suspected as a possible etiology of a patient's lung injury, obtain detailed history regarding:
 - Substance(s) used: nicotine, cannabinoids (e.g., marijuana, THC, THC concentrates, CBD, CBD oil, synthetic cannabinoids [e.g., K2 or spice], hash oil, Dank vapes), flavors, or other substances
 - Substance source(s): commercially available liquids (i.e., bottles, cartridges, or pods), homemade liquids, and re-use of old cartridges or pods with homemade or commercially bought liquids
 - Device(s) used: manufacturer; brand name; product name; model; serial number of the product, device, or e-liquid; if the device can be customized by the user; and any product modifications by the user (e.g., exposure of the atomizer or heating coil)
 - Where the product(s) were purchased
 - Method of substance use: aerosolization, dabbing, or dripping
 - Other potential cases: sharing e-cigarette or vaping products (devices, liquids, refill pods, or cartridges) with others
6. Determine if any remaining product, including devices and liquids, are available for testing. Testing can be coordinated with the local or state health departments.
7. Consider all possible causes of illness in patients reporting respiratory and gastrointestinal symptoms. Evaluate and treat for other possible causes of illness (e.g., infectious, rheumatologic, neoplastic) as clinically indicated. Consider consultation with specialists (pulmonary, infectious disease, critical care, medical toxicology) as appropriate.
8. Clinical improvement of patients with lung injury associated with e-cigarette use has been reported with the use of corticosteroids. The decision to use corticosteroids should be made on a case-by-case basis based on risks and benefits and the likelihood of other etiologies.
9. Lipoid pneumonia associated with inhalation of lipids in aerosols generated by e-cigarettes or vaping products has been reported based on the detection of lipid-laden alveolar macrophages obtained by bronchoalveolar lavage (BAL) and lipid staining (e.g., Oil Red O, Sudan Black). The decision about whether to perform a BAL should be based on individual clinical circumstances.
10. Lung biopsies have been performed on some patients. If a lung biopsy is obtained, lipid staining may be considered during pathologic examination, and is best performed on fresh tissue. Routine pathology tissue processing (including formalin-fixation and paraffin-embedding) can remove lipids. Conducting routine tissue processing and histopathologic evaluation is still important. Consider consultation with specialists in pulmonary medicine and pathology to help inform any evaluation plan.
11. Patients who have received treatment for lung injury related to e-cigarette or vaping product use should undergo follow-up evaluation as clinically indicated to monitor pulmonary function.

12. Consider asking the medical examiner or coroner's office and hospital pathologists to report possible deaths, especially those without an alternative, likely diagnosis. If individuals are identified after death or at autopsy who showed signs of lung injury as described above, medical examiners and coroners are encouraged to report the cases to their local or state health department.

If a lung biopsy or autopsy is performed on a patient suspected of lung injury related to e-cigarette, or vaping, product use, consider submission of fixed lung biopsy tissues or autopsy tissues to CDC for evaluation. Testing can include evaluation for lipids on formalin-fixed (wet) lung tissues that have not undergone routine processing. Routine microscopic examination will be performed, as well as infectious disease testing, if indicated, on formalin-fixed (wet) tissues, or formalin-fixed, paraffin-embedded tissue specimens.

OTHER CONSIDERATIONS

Clinicians routinely consider multiple possible etiologies when evaluating and treating patients presenting with respiratory symptoms. In some cases, treatment directed at one or more of these etiologies must be initiated before the results of diagnostic testing, or other clinical features enable the list of possibilities to be narrowed.

- For the coming flu season, CDC recommends that clinicians strongly consider respiratory infections such as influenza, as well as lung injury associated with e-cigarette use, or vaping, in all patients presenting with respiratory symptoms and a history of e-cigarette use, or vaping.
- Clinicians are further advised that it may not be possible to definitively distinguish between respiratory infection and lung injury associated with use of e-cigarettes, or vaping, using available testing. Therefore, therapy directed at both may be necessary. Decisions on the initiation or discontinuation of treatment should be based on specific clinical features and, when appropriate, in consultation with specialists.

Chapter 363

OUTBREAK OF LUNG INJURY ASSOCIATED WITH E-CIGARETTE PRODUCT USE OR VAPING: INFORMATION FOR CLINICIANS*

Centers for Disease Control and Prevention

CDC 2019 Lung Injury Response

BACKGROUND

- As of September 17, 2019, 530 cases of lung injury associated with the use of e-cigarette products or vaping have been reported to CDC
 - data updated weekly at CDC's outbreak website
 - 38 states, 1 U.S. territory; 7 deaths have been confirmed
- No specific etiology has been identified, but all patients have reported using e-cigarette products, or vaping
 - Most have reported using products containing THC
 - Many have reported using THC and nicotine; some only nicotine
- CDC issued recommendations for clinicians, public health officials, and the public through its health advisory network (HAN) on August 30, 2019
- Initial clinical experience summarized in recent publications in *Morbidity & Mortality Weekly Report (MMWR)* and *New England Journal of Medicine (NEJM)*

* This is an edited, reformatted and augmented version of Centers for Disease Control and Prevention, dated September 16, 2019.

Patient Exposures in the Lung Injury Outbreak

- All have reported use of e-cigarette products, or vaping, within 90 days of illness
 - Most have reported using cannabinoids such as Δ -9-tetrahydrocannabinol (THC) or cannabidiol (CBD)
 - Some have reported nicotine use alone
- No single device type has been reported consistently (though device types have not yet been well-characterized)
- No single e-cigarette product or substance (including cannabis products) has been reported consistently

CDC Confirmed Case Definition (September 18, 2019)

- Using an e-cigarette ("vaping") or dabbing* in 90 days prior to symptom onset
- AND**
- Pulmonary infiltrate, such as opacities, on plain film chest radiograph or ground-glass opacities on chest CT
- AND**
- Absence of pulmonary infection on initial work-up. **Minimum criteria** are
 - A negative respiratory viral panel **and**
 - A negative influenza PCR or rapid test, if local epidemiology supports influenza testing; **and**
 - All other clinically-indicated respiratory ID testing (e.g., urine Antigen for *Streptococcus pneumoniae* and *Legionella*, sputum culture if productive cough, bronchoalveolar lavage (BAL) culture if done, blood culture, HIV-related opportunistic respiratory infections if appropriate) are negative
- AND**
- No evidence in medical record of alternative plausible diagnoses (e.g., cardiac, rheumatologic, or neoplastic process)

CDC Probable Case Definition (September 18, 2019)

- Using an e-cigarette ("vaping") or dabbing* in 90 days prior to symptom onset
- AND**
- Pulmonary infiltrate, such as opacities, on plain film chest radiograph or ground-glass opacities on chest CT
- AND**
- Infection identified via culture or PCR, but clinical team** believes this infection is not the sole cause of the underlying lung injury **OR Minimum criteria** to rule out pulmonary infection not met (testing not performed) and clinical team** believes this infection is not the sole cause of the underlying lung injury

** Clinical team caring for the patient.

AND

- No evidence in medical record of alternative plausible diagnoses (e.g., cardiac, rheumatologic, or neoplastic process)

Patient Exposures in the Lung Injury Outbreak

- Series of 53 cases from Illinois and Wisconsin*
 - All had history of e-cigarette use and related products
 - 41 extensively interviewed
 - 61% reported nicotine use; 80% reported THC use; 7% reported CBD use
 - 37% reported THC use alone; 17% reported nicotine use alone
 - 44% reporting both nicotine and THC product use
 - Various brands and flavors
- Among patients with additional data, 94% used within week before symptom onset; 88% reported daily use

E-CIGARETTE OR VAPING PRODUCTS

E-Cigarette or Vaping Products: The Basics

- E-cigarette products include devices, liquids, flavorings, refill pods, and cartridges
- Devices heat liquid to produce an aerosol that is inhaled by the user
- E-cigarette **aerosol** can contain harmful or potentially harmful substances

* Layden J, et al. Pulmonary illness related to e-cigarette use in Illinois and Wisconsin—preliminary report. *NEJM* 2019.

- Nicotine
- Heavy metals (e.g., lead, nickel, tin)
- Volatile organic compounds
- Ultrafine particles
- Cancer-causing chemicals
- Flavoring (e.g., diacetyl)

E-Cigarette Products: Devices

- Devices vary in shape, size, type, and manufacturer
- Common names
 - E-cigs
 - Vapes
 - E-hookahs
 - Vape pens
 - Mods
 - Tanks
 - Electronic nicotine delivery systems

E-Cigarette Products: Liquids, Cartridges, and Pods

- E-cigarette **liquid** can contain
 - Nicotine
 - Flavorings
 - Propylene glycol and vegetable glycerin used in varying proportions as carriers
 - Other chemicals also present
 - Cannabinoids: Δ -9-tetrahydrocannabinol (THC), cannabidiol (CBD), butane hash oil (BHO)
 - Other substances
- E-cigarette liquid types
 - Commercial refillable e-liquid
 - Commercial non-refillable e-liquid
 - Homemade or street sources

E-CIGARETTE PRODUCTS: BEHAVIORS

- Hacking: modifying device in a way not intended by the manufacturer
 - Refilling single-use cartridges (e.g., with homemade or illicit substances)
 - Dripping: dropping liquid directly onto device heating coil to attain higher compound concentrations in the aerosol
- Dabbing: superheating substances containing high concentrations of THC or other cannabinoids (e.g., budder, BHO, 710, CBD)

CLINICAL FEATURES: FREQUENT CLINICAL, LABORATORY, RADIOGRAPHIC, AND PATHOLOGIC FINDINGS AND OUTCOMES

Information Sources on Clinical Features

- Anecdotal and verified reports from health departments
- Formal and informal discussions between CDC, clinicians, and medical professional societies
- Recent publications in *Morbidity and Mortality Weekly Report* and *New England Journal of Medicine* (published September 6, 2019)
 - Schier JG, et al. Severe Pulmonary Disease Associated with Electronic-Cigarette-Product Use — Interim Guidance. *MMWR* 2019;68(36).
 - Layden J, et al. Pulmonary illness related to e-cigarette use in Illinois and Wisconsin—preliminary report. *NEJM* 2019.
 - Davidson K, et al. Outbreak of e-cigarette-associated acute lipoid pneumonia—North Carolina, July–August 2019. *MMWR* 2019;68(36).
 - Maddock S, et al. Pulmonary lipid-laden macrophages and vaping. *NEJM* 2019.
 - Henry TS, et al. Imaging of vaping-associated lung disease. *NEJM* 2019

FREQUENT CLINICAL SYMPTOMS

- Most patients have been young and otherwise healthy
- Report gradual onset of various symptoms over days to weeks
 - Respiratory (cough, chest pain, shortness of breath)
 - Gastrointestinal (GI) (abdominal pain, nausea, vomiting, diarrhea)
 - Systemic symptoms (fatigue, fever, weight loss)
- GI symptoms sometimes precede respiratory symptoms
 - Tend to resolve quickly after admission
 - Evaluation for GI-related illness unrevealing
- Almost all published cases have been hospitalized
 - Many with ≥ 1 antecedent evaluation in ambulatory settings

Frequent Presenting Signs upon Hospital Admission

- Fever
- Tachycardia
- Tachypnea
- Hypoxemia (even in patients without respiratory symptoms upon presentation)
 - One of 53 patients in the recently published 53-case series in *New England Journal of Medicine** did not report respiratory symptoms, but had oxygen saturation of 91% on room air on admission

FREQUENT LABORATORY AND RADIOGRAPHIC FINDINGS

- Laboratory
 - Serum leukocytosis with neutrophil predominance
 - Elevated serum markers of inflammation (e.g., ESR, CRP)
 - Transient, mild elevation in serum transaminases
- Chest imaging
 - Abnormal findings may or may not be present on initial imaging, but develop eventually
 - Bilateral opacities on plain radiograph or ground-glass opacities on chest computed tomography (CT), often with sub-pleural sparing
- Imaging of abdomen/pelvis usually unremarkable except for bilateral opacities in cuts of lower lung fields included on CT

* Layden J, et al. Pulmonary illness related to e-cigarette use in Illinois and Wisconsin—preliminary report. *NEJM* 2019.

Clinical Course

- Initial therapies focused on presumed infectious etiologies
 - Empiric antibiotics with or without steroids
 - Observation with supportive therapy other than antibiotics or steroids
- Many patients have experienced sub-acute or acute hypoxemic respiratory failure requiring supplemental oxygenation and at times ventilatory support, including with intubation and mechanical ventilation or extracorporeal membrane oxygenation
- Patients who did not respond to antibiotics alone have tended to respond to systemic corticosteroids (either alone or concurrent with antibiotics)

Frequently Performed Diagnostic Evaluations

- Appropriate extensive evaluations for infectious etiologies often completed without an identified cause
- Use of pulmonary function testing has been highly variable, mostly depending upon institutional practices
- Some patients evaluated for lung injury with bronchoscopy with bronchoalveolar lavage or lung biopsy (either transbronchial or surgical via video-assisted thoracoscopic surgery [VATS] or thoracotomy)
 - Additional patients considered for these procedures but were too ill
 - Roles and frequencies of biopsy methods remain unknown

Evaluation of Pathologic Specimens

- Both routine histopathologic and special evaluations of specimens have been performed
- Routine processing of tissues includes the application of alcohol, which removes lipids
- Therefore, as a special evaluation, lipid-staining (e.g., Oil Red O, Sudan Black) has been performed on fresh tissues and bronchoalveolar lavage fluid

Spectrum of Clinical and Pathologic Diagnoses

- Acute lung injury and adult respiratory distress syndrome (ARDS)
- Diffuse alveolar damage
- Lipoid pneumonia
- Acute necrotizing pneumonitis
- Organizing pneumonia with lipid-laden macrophages
- Non-specific inflammation
- Hypersensitivity pneumonitis
- Eosinophilic pneumonia

Outcomes

- Specialists in pulmonary medicine, critical care, infectious diseases, pathology, or toxicology frequently involved in patients' care
- Despite illness severity, most patients have survived to hospital discharge
 - Most patients have been young and healthy pre-illness
 - Some patients who have not recovered to pre-illness pulmonary function at time of discharge, demonstrated improvement during post-hospitalization evaluation
 - Other patients still had reduced pulmonary function during post-hospitalization evaluation
 - 7 patients died in the hospital (as of September 17, 2019)

RECOMMENDATIONS FOR CLINICIANS

Overview

- History
- Diagnosis
- Clinical Management
- Evaluation of Pathologic Specimens at CDC
- Autopsy
- What to Tell Patients
- Case Reporting to Public Health Authorities
- CDC will provide updates as more information becomes available

History

- Ask patients who report e-cigarette product use, or vaping, within the last 90 days about signs and symptoms of respiratory illness
- Ask patients who present with signs and symptoms of respiratory illness about e-cigarette use, or vaping, within the last 90 days
- If e-cigarette product use is suspected as a possible etiology of a patient's respiratory illness, obtain a detailed history about e-cigarette product use, or vaping

E-Cigarette Product Use

- Substances used: nicotine, cannabinoids (e.g., marijuana, THC, THC concentrates, CBD, CBD oil, synthetic cannabinoids [e.g., K2 or spice], hash oil, Dank vapes), flavors, or other substances
- Substance sources: commercially refillable e-liquids (e.g., bottles, cartridges, or pods), commercial non-refillable e-liquids, homemade or street sources

- Devices used: manufacturer; brand name; product name; model; serial number of the product, device, or e-liquid; if the device can be customized by the user; and any product modifications by the user (e.g., exposure of the atomizer or heating coil)
 - Where the devices were purchased
 - Method of use: aerosolization, dabbing, dripping, or re-use of old cartridges or pods with homemade or commercially bought e-liquids
 - Sharing e-cigarette products (devices, liquids, refill pods, or cartridges) with others (to identify other cases)

Diagnosis

- Consider all possible causes of illness (e.g., infectious, rheumatologic, neoplastic) in patients reporting respiratory with or without GI symptoms and e-cigarette product use
- Consider consultation with specialists (pulmonary, infectious disease, critical care, medical toxicology, pathology) as clinically indicated
- Lipoid pneumonia associated with inhalation of lipids in aerosols generated by e-cigarettes, or vaping, has been reported based on the detection of lipid-laden alveolar macrophages obtained by bronchoalveolar lavage and lipid staining (e.g., Oil Red O, Sudan Black)
 - The decision about whether to perform bronchoalveolar lavage, with or without transbronchial biopsy, should be based on the overall clinical picture
- Lung biopsies have been performed on some patients
 - The decision about whether to perform biopsy (whether transbronchial or surgical) should be based on the overall clinical picture.
 - If a lung biopsy is obtained, consider lipid-staining during pathologic examination.* Because routine tissue processing involves the application of alcohols, which remove lipids, lipid-staining is best performed on fresh tissue.
 - Before the procedure consider consultation with pulmonary, critical care, pathology, or other specialties to inform any evaluation plan
 - However, conducting routine tissue processing and histopathologic evaluation is still important.
- Contact public health officials as needed for technical assistance with laboratory testing, including for guidance regarding whether to retain specimens, storage instructions in the event of long-term storage, and collection of specimens for indications other than clinical care
- If retaining of specimens is anticipated, contact your facility's laboratory since routine practice might result in discarding of specimens before desired

* Additional information on lipid-staining is available at: https://www.cdc.gov/tobacco/basic_information/e-cigarettes/severe-lung-disease/healthcare-providers/index.html.

Clinical Management

- Decisions regarding outpatient versus inpatient management should be based on individual clinical circumstances
- Evaluate and treat as appropriate for other possible causes of illness (e.g., infectious, rheumatologic, neoplastic)
- Consider consultation with specialists (pulmonary, infectious disease, critical care, medical toxicology)
- Clinical improvement of patients with lung injury associated with e-cigarette use, or vaping, has been reported with the use of corticosteroids
 - Dosing, route of administration, duration, and timing have varied
 - The decision to use corticosteroids should be made on a case-by-case basis based on risks and benefits and the likelihood of other etiologies
- Patients who have received treatment for lung injury related to e-cigarette product use, or vaping, should undergo follow-up evaluation as clinically indicated to monitor pulmonary function

Evaluation of Pathologic Specimens at CDC*

- If feasible, submission of formalin-fixed (wet) lung tissues is encouraged
- CDC's Infectious Disease Pathology Branch can perform lipid-staining on formalin-fixed (wet) lung tissues using osmium tetroxide before routine tissue processing and paraffin embedding
 - However, lipid staining cannot be performed on formalin-fixed, paraffin-embedded lung tissue blocks, because they have undergone processing that removes lipids
- CDC's Infectious Disease Pathology Branch will also review tissue histopathology and perform additional testing, including testing for possible infectious etiologies
- Please first report any possible cases of lung injury associated with e-cigarette product use, or vaping, to your state, territorial, tribal, or local health department
- Pre-approval is required prior to submission of any tissue specimens. For pre-approval, health departments should contact pathology@cdc.gov and [Vaping AssocIllness@cdc.gov](mailto:VapingAssocIllness@cdc.gov).

Autopsy

- In the event of a fatal outcome, autopsies can be considered
 - Collection of fresh lung tissue for staining of lipids, formalin-fixed (wet) lung tissue, and submission of lung and other tissues for routine tissue processing, paraffin-embedding, and evaluation of histopathology should be considered

* Additional information on lipid-staining is available at: https://www.cdc.gov/tobacco/basic_information/e-cigarettes/severe-lung-disease/healthcare-providers/index.html.

- Infectious disease testing, including postmortem microbiology and molecular testing, should also be considered if indicated by patient history or autopsy findings
- Contact public health officials as needed for technical assistance with laboratory testing

What to Tell Patients

- Regardless of the ongoing investigation, e-cigarette products should not be used by
 - Youth and young adults
 - Pregnant women
 - Adults who do not currently use tobacco products
- Regardless of the ongoing investigation, anyone who uses e-cigarette products should
 - Not buy these products off the street (e.g., e-cigarette products with THC, other cannabinoids)
 - Not modify e-cigarette products or add any substances to these products that are not intended by the manufacturer
 - Monitor yourself for symptoms (e.g., abdominal pain, nausea, vomiting, diarrhea, cough, shortness of breath, chest pain)
 - Promptly seek medical attention if you have concerns about your health
- For adults trying to quit tobacco product use, including e-cigarettes
 - Use evidence-based treatments, including counseling from a healthcare provider and FDA-approved medications
- During the current investigation of lung injury associated with e-cigarettes, or vaping, if you are concerned about these specific health risks
 - Consider refraining from using e-cigarette or vaping products
 - If you are an adult who uses e-cigarettes because you have quit cigarette smoking, do not return to smoking cigarettes
 - If you continue to use e-cigarettes, carefully monitor yourself for symptoms and see a healthcare provider right away if you have symptoms like those reported in this outbreak
- If you are concerned about harmful effects from e-cigarette products, call your local poison control center at: 1-800-222-1222
- Submit detailed reports of any unexpected tobacco or e-cigarette-related health or product issues to the FDA via the online Safety Reporting Portal: <https://www.safetyreporting.hhs.gov> external icon

Case Reporting to Public Health Authorities

- Report cases of lung injury of unclear etiology and a history of e-cigarette product use, or vaping, within the past 90 days to your state or local health department

- Reporting of cases may help CDC and state health departments determine the cause or causes of these pulmonary illnesses
- Determine if any remaining product, including devices and liquids, are available for testing
 - Coordinate testing with the local or state health departments

Additional Resources

- CDC will provide updates as more information becomes available
- CDC website with updates for the ongoing investigation of lung injury associated with e-cigarette products use, or vaping: https://www.cdc.gov/tobacco/basic_information/e-cigarettes/severe-lung-disease.html.

LIMITATIONS AND KNOWLEDGE GAPS

- Information sources have included both confirmed and unconfirmed reports and small case series
 - Anecdotal data can generate hypotheses but alone are insufficient; clinical information to support range of diagnoses has been lacking
 - As of September 17, 2019, of 530 reported cases, <20% have been described in published literature; representativeness of published cases is unknown
- Outbreak surveillance case definitions are intended for public health data collection purposes and not intended for use as a clinical diagnostic tool or replacement for individual clinical judgment
 - No diagnostic criteria exist
- Most cases have been severe illness resulting in hospitalization, but true spectrum of illnesses (including less severe illness) could be unrecognized
- Investigations in affected states have been ongoing, but national efforts to coordinate, centralize, and standardize data collection efforts have been underway since August 16, 2019
- No systematic data yet for exposure (including products, quantities, sources) or clinical information
- Available data point away from a purely infectious etiology, but this does not exclude the possibility of concurrent processes
 - No decision-making tools to distinguish infection versus non-infection at presentation, so important to rule out and empirically treat infectious etiologies as appropriate, even in patients with exposure history
 - Patterns of illness could change with the approaching respiratory virus season
- Remains unclear whether this is a new syndrome or a newly recognized one previously thought to be pneumonia or pneumonitis of unclear etiology

- Although most patients have survived to hospital discharge, whether there are post-illness sequelae (e.g., reduced pulmonary function) after hospital discharge is not yet known for most patients
- Age-related differences in illness have not been assessed
 - Outbreak predominantly has affected younger, healthy patients, possibly reflecting different use patterns conferring increased risk compared with older patients
 - Alternatively, diagnosis could be more complicated in adults who are more likely to have chronic lung disease or other medical comorbidities, leading to under-recognition of illness in adults
 - Unclear whether adults have more severe illness more likely to result in death
- Lipoid pneumonia has been reported in historical and recent case reports and series, but important caveats remain
 - Clinical significance of lipid-laden macrophages remains undetermined— are these markers of disease or markers of exposure?
 - Bronchoalveolar lavage has not been obtained universally on bronchoscope evaluation, and in turn nor has lipid-staining (a non-routine procedure), so frequency of finding is uncertain
 - Characteristics of cellularity of bronchoalveolar lavage fluid are uncertain because they could be altered by antibiotics or steroids and influenced by timing of therapies and interventions
- Autopsy has not been performed for all cases resulting in death, and results have not been reported for all cases when performed

Summary

- CDC's investigation has not yet identified any specific substance or e-cigarette product linked to all cases
 - Most patients have reported using cannabinoids such as THC or CBD
 - Some have reported nicotine use alone
- Most patients have been hospitalized with respiratory illness and received treatment for presumed infectious etiologies; some have responded to steroids with or without antibiotics
- Report possible cases to and coordinate product testing with your health department
- CDC will provide updates as information becomes available
https://www.cdc.gov/tobacco/basic_information/e-cigarettes/severe-lung-disease/healthcare-providers/index.html

APPENDIX: REVIEW OF RECENT AND HISTORICAL LITERATURE

Recent Publications on Pulmonary Disease Associated with E-Cigarette Product Use, or Vaping

Recent Publications with Case Findings

Reference	Number of patients	Brief Description
Layden J, et al. Pulmonary illness related to- e cigarette use in Illinois and Wisconsin— preliminary report. <i>NEJM</i> 2019	53	Summary of clinical characteristics and use of e-cigarette products reported among initial reported cases in Wisconsin and Illinois
Davidson K, et al. Outbreak of e-cigarette-associated acute lipoid pneumonia—North Carolina, July–August 2019. <i>MMWR</i> 2019;68(36).	5	Description of patients with lipoid pneumonia diagnosed at 2 hospitals in North Carolina
Maddock S, et al. Pulmonary lipid-laden macrophages and vaping. <i>NEJM</i> 2019.	6	Summary of clinical characteristics and bronchoalveolar lavage findings for patients in Utah
Henry TS, et al. Imaging of vaping-associated lung disease. <i>NEJM</i> 2019	19 (+15 in literature)	Review of imaging findings

Comparison of Patients in North Carolina and Illinois/Wisconsin

Patient Characteristics in North Carolina, Illinois, and Wisconsin

Characteristic	NC (n=5)	IL/WI (n=53)
Ages (years)	18–35	16–53 (median:19)
Male	Not reported	44/53 (83%)
Hospitalized	5/5	50/53 (94%)

Reported Symptoms in North Carolina, Illinois, and Wisconsin

Symptom	NC (n=5)	IL/WI (n=53)
Shortness of breath	5/5	46/53 (87%)
Nausea or vomiting	5/5	37/53 (70%)
Abdominal pain or discomfort	5/5	23/53 (43%)
Diarrhea	Not reported	23/53 (43%)
Subjective fever	5/5	43/53 (81%)
Any systemic symptoms*	Not reported	53/53 (100%)

* Subjective fever, chills, weight loss, fatigue or malaise.

Presentation Findings in North Carolina, Illinois, and Wisconsin

Finding	NC (n=5)	IL/WI (n=53)
Fever	Not reported	15/51 (29%)
Hypoxemia	5/5 with sat <90% on room air (RA)	20/52 (38%) with sat <95% on RA; 16/52 (31%) with sat <89% on RA
CXR with bilateral infiltrates	5/5 on initial	48/53 (91%) on initial
CT chest with bilateral opacities	5/5 (timing not specified)	48/48 (100%) on initial
Elevated white-cell count	5/5, all with neutrophil predominance; none with eosinophils	45/52 (87%); 34/36 (94%) with neutrophil predominance; none with eosinophils

Clinical Course in North Carolina, Illinois, and Wisconsin

Finding	NC (n=5)	IL/WI (n=53)
Received empiric antibiotics	5/5	45/50 (90%)
Worsened on antibiotics	5/5	Not reported
Received steroids	5/5	46/50 (92%)
Improved on steroids (with or without antibiotics)	5/5	30/46 (65%)
Negative workup for infectious etiologies	5/5	"Nearly all"
Required ICU care	3/5	31/53 (58% overall, 62% of hospitalized)
Diagnosed with ARDS	3/5	15/53 (28%)
Required intubation and mechanical ventilation	1/5	17/53 (32% overall, 35% of hospitalized)
Received extracorporeal membrane oxygenation	0/5	2 (1 died)
Survived to discharge	5/5	52/53 (98%)

Comparison of Bronchoalveolar Lavage Findings for Patients in North Carolina, Illinois/Wisconsin, and Utah

Bronchoscopy Alveolar Lavage Findings in North Carolina, Illinois, Wisconsin, and Utah

Characteristic	NC (n=3)	IL/WI (n=24)	UT (n=6)
Lipid staining performed	3/3	Not specified	6/6
Lipid-laden macrophages identified	3/3	7/14 with cell counts reported	6/6
>5% eosinophils*	0/3	0/3	1/6

Review of Imaging Studies for 19 Patients and Review of Literature

Henry TS, et al. Imaging of vaping-associated lung disease. *NEJM* 2019

Review of Imaging Studies (Correspondence from Henry et al.)

- Based on review of imaging for 19 patients and 15 patients reported in literature

* Timing of steroids or other interventions not specified.

- No information provided regarding exposure other than “*all met the case definition of vaping-associated lung injury*”
- Most imaging patterns have basilar-predominant consolidation and ground-glass opacity, often with areas of lobular or subpleural sparing
- Authors noted that fat attenuation (highly suggestive of lipoid pneumonia) has not been frequently observed on CT

Additional Data from Wisconsin and Illinois

Layden J, et al. Pulmonary illness related to e-cigarette use in Illinois and Wisconsin—preliminary report. *NEJM* 2019

Experience in Illinois and Wisconsin (n=53 patients)

- Patient demographics
 - Median age 19 years (range: 16–53 years)
 - 83% male
 - 30% with asthma; otherwise no underlying chronic lung disease
- Clinical presentations
 - Median symptom duration before admission 6 days (range: 0–61 days)
 - 94% of patients hospitalized; 72% evaluated as outpatient before admission
 - 45% of those evaluated as outpatients received outpatient antibiotic treatment, however all reported progression of symptoms

Clinical Presentation

- Respiratory symptoms (98% of cases)
 - Shortness of breath (87%)
 - No report of upper respiratory symptoms (e.g., rhinorrhea, sneezing, congestion)
- GI symptoms (81% of cases)
 - Nausea (70%)

- Vomiting (66%)
- Diarrhea (43%)
- Systemic symptoms (100% of cases)
 - Subjective fever (81%)
- Initial recorded vital signs
 - 64% with tachycardia (range 55–146 BPM)
 - 43% with tachypnea (range: 15–48 breaths/min)
 - 69% with SpO₂ <95% on room air
 - 31% with SpO₂ <89% on room air
 - 29% with fever
- Initial laboratory findings
 - 87% with leukocytosis (median: 15.9K/ml, range 12.3–18.1K/ml); 94% with neutrophil predominance; no eosinophilia >2%
 - 50% with mild transient transaminase elevations
 - Acute kidney injury reported in 1 patient who responded to intravenous fluid (IVF) hydration

Imaging

- 91% with abnormal findings on chest radiograph at presentation
- All 48 patients who had CT chest had abnormal findings
- Characteristic finding: bilateral ground-glass opacities with subpleural sparing
- All patients had bilateral lung opacities

Biopsy Findings

- 3 patients underwent lung biopsy
 - 2 patients transbronchial only, 1 patient also had open lung biopsy
 - 2 on antibiotics/corticosteroids, 1 on neither before biopsy
 - Lipid staining not performed
 - Findings: mild and non-specific damage, acute diffuse alveolar damage and foamy macrophages suggesting inhalation toxin exposure, interstitial and peribronchiolar granulomatous pneumonitis

Dosing of Corticosteroids in Recent Outbreak Reports

Publication	Dosages and medications
Davidson K, et al. Outbreak of e-cigarette-associated acute lipid pneumonia—North Carolina, July–August 2019. <i>MMWR</i> 2019;68(36).	5/5 patients received intravenous methylprednisone (120 mg–500 mg daily); all discharged home on taper of oral prednisone (dose and duration not specified)
Maddock S, et al. Pulmonary lipid-laden macrophages and vaping. <i>NEJM</i> 2019.	2/6 patients received “high-dose glucocorticoids” (dose, duration, and discharge regimen not specified); 2 other patients received “short-course of prednisone” before hospitalization (dose and duration not specified)
Layden J, et al. Pulmonary illness related to e-cigarette use in Illinois and Wisconsin—preliminary report. <i>NEJM</i> 2019	“majority of patients have received prolonged courses” of systemic glucocorticoid therapy

ABSTRACT

Nigeria – a pluralistic society – is a sub-Saharan Africa country, home to about 200 million people from 371 cultural tribes. All tribes in Nigeria have their specific cultural beliefs and practices. As a matter of fact, many of these practices had been in existence for hundreds of years, even before British colonization (1800-1960). There exists a strong interrelationship between the society and health. Some practices in the society have negative health implications while some do not. Unfortunately, many of the traditional or cultural practices in the Nigerian society have more associated harms than benefits. In

* Corresponding Author's Email: kehindekanmodi@gmail.com.

this book we have gathered research that describes health and health aspects of modern Nigeria, which we hope will be of interest to the reader.

INTRODUCTION

It is a popular saying that health is wealth. This statement is actually true. The health of a person goes far a long way in determining their wealth. Similarly, a healthy society is a wealthy society.

Figure 1. Map of Nigeria showing all the 36 states with the federal capital territory.

A society, according to the Cambridge dictionary is “a large group of people who live together in an organized way, making decisions about how to do things and sharing the work that needs to be done” [1]. All the people in a country, or in several similar countries, can be referred to as a society [1].

NIGERIAN SOCIETY

There are 36 states in Nigeria, excluding the Federal Capital Territory (FCT) which is situated in Abuja (see figure 1) [2]. These 36 states spread across the six geopolitical zones of the country (see Table 1). The Nigerian political system is democracy, adopting the United States presidential structure of governance [3].

Nigeria – a pluralistic society – is a sub-Saharan Africa country, home to about 200 million people from 371 cultural tribes [4, 5]. Amongst all the cultural tribes in Nigeria, Yoruba, Hausa/Fulani and Igbo are the three major tribes [5]. The northern part of Nigeria is

predominantly occupied by the Hausa/Fulani ethnic group while the southern part of Nigeria is predominantly occupied by the Yoruba and the Igbo ethnic groups [5].

Table 1. Geopolitical zones of Nigeria

Geopolitical zone	State
South-west	Osun, Oyo, Ondo, Ogun, Ekiti, Lagos
South-east	Abia, Anambra, Ebonyi, Enugu, Imo
South-south	Akwa Ibom, Bayelsa, Cross River, Edo, Delta, Rivers
North-central	Benue, Kogi, Nasarawa, Plateau, Niger, Kwara, Federal Capital Territory
North-east	Borno, Bauchi, Gombe, Taraba, Yobe, Adamawa
North-west	Sokoto, Kebbi, Zamfara, Katsina, Kaduna, Jigawa, Kano

CULTURAL BELIEFS AND PRACTICES IN NIGERIA

All tribes in Nigeria have their specific cultural beliefs and practices. As a matter of fact, many of these practices had been in existence for hundreds of years, even before British colonization (1800-1960) [6]. Health-wise, some beliefs and practices are favorable, while some are not [6, 7]. In this chapter, we shall briefly mention some popular cultural beliefs and practices and their health implications in the Nigerian society (see Table 2).

Table 2. Examples of popular cultural beliefs and practices in Nigeria

Part of Nigeria	Beliefs/practice	Purpose/understanding	Health implication
Northern	Sakkiya	To cure body swelling	Negative; controversial
Northern	Kawo	To cure body swelling	Negative; controversial
Northern	Kamun wuta	To cure severe burns	Negative; controversial
Northern	Dauri	To treat limb fracture	Negative; controversial
Southern	Te Magun	To punish women who are not faithful in their marriage	Negative
Southern	Eji beauty	Epitome of feminine beauty	Nil

In the Hausa culture, for instance, there is a popular traditional practice called Sakkiya [8]. Sakkiya is an act of using a hot pointed metallic tip to puncture a body swelling with the hope of achieving a curative effect [8]. This procedure is widely practiced in rural villages in northern Nigeria commonly by the blacksmith (called Makera) and traditional barbers (called wanzami) [9]. Scientific investigations has shown that this traditional practice can be lethal due to its queried safety profile and associated complications that may arise from it [7, 10]. Also, there exist some other traditional practices in this region such as Kawo, Kamun wuta, Dauri, etc. The Kawo practice involves the use of the human mouth to suck out the fluid content in a body swelling via horn of a ram (the horn of the ram serves as a straw to suck the fluid). Kamun wuta is a spiritual procedure that involves the use of special ritual and the application of locally prepared special powder on severe burns; this procedure is being done by Malams (spiritualists), it is not hygienic and it is done with the purpose of curing burns. Dauri is known as traditional bone setting and it involves the use of sticks and bandages to

support fractured limbs. Dauri is being done by Malams. These cultural practices towards are crude and harmful to human health.

In the Yoruba culture, there is a popular practice called “te Magun”(“te” means placing while Magun refers to “thunderbolt”). This practice the placing of magical thread on door threshold for a woman to inadvertently walk over it and be under the spell; if any woman walks over it and she fails to have penetrative vaginal intercourse with any man within seven days after, she will emaciate and dry; however, if she does, the man will die after the intercourse. For the men that fell victim of such, they may crow or somersault three times, and die immediately. The “te Magun” is used in the Yoruba culture to punish married women who are not faithful to their spouse. Also, there is a belief that midline diastema (called “Eji” in Yoruba language) is a mark of epitome of beauty. Women with “Eji” are more appealing to the men in the Yoruba society than those without “Eji”. Due to this societal perception on “Eji”, some women do patronize quacks who are parading themselves as dentist to have a gap created in-between their upper central incisors. In the course of getting a gap tooth, some women sustain/develop dental traumas and/or odontogenic infections.

In the Igbo culture, the midline diastema (“Eji” belief in Yoruba culture) is also believed to be a mark of magnificent beauty among Igbo women. Some Igbo women do seek quacks for gap creation in between their teeth; unfortunately, this practice has negative oral health implications (such as tooth fracture, dentinal hypersensitivity) that can be incurred.

CONCLUSION

There exists a strong interrelationship between the society and health. Some practices in the society have negative health implications while some do not. Unfortunately, many of the traditional or cultural practices in the Nigerian society have more associated harms than benefits.

ABSTRACT

Many cancer patients in Nigeria present very late at hospitals for treatment. Studies have shown that the delay is due to the belief that their cancer disease is of a spiritual cause. In this chapter we explore the opinions of religious leaders and seminarians in Ibadan City, Oyo State, Nigeria, on the top five aetiology/risk factors of cancer. Methods: A cross-sectional study was done among 302 religious leaders and seminarians in Ibadan. Study tool was an anonymous questionnaire. Data collected was analysed using SPSS version 16 software. Results: The top five cancer aetiology/risk factors, as indicated by the respondents, were as follows: toxic drugs (58.9%); genetic factors (53.6%); radiation exposure (52%); poison (42.4%); poverty (34.8%). Conclusion: The opinion of the majority of the surveyed religious leaders and seminarians favoured biological, physical and chemical factors as the commonest cancer aetiology/risk factors, although the minority were of the opinion that cancer can also be caused by socioeconomic factors and supernatural forces.

* Corresponding Author's Email: kanmodikehinde@yahoo.com.

INTRODUCTION

The prevalence of cancer disease is on the increase among Nigerians, and also among the inhabitants of other developing nations [1, 2]. As far back as 2008, about 12.7 million cancer cases and 7.6 million cancer deaths have been reported worldwide, of which 56% of these cases and 64% of these deaths occurred in the developing countries, Nigeria inclusive [3].

It is so unfortunate that many cancer patients in Nigeria do delay their presentation at hospitals, unlike those in the developed world [4-8]. Many of these patients do present at the hospital when their cancer disease is already at its advanced stage [4, 6-8]. As a matter of fact, one of the main reasons for their delay in seeking hospital care is that many of them ascribed their cancer disease to spiritual causes [4, 6, 7] and many of these patients had first sought spiritual healing by visiting prayer houses, traditional healers, and spiritualists, before eventually presenting at the hospital after their attempts towards achieving spiritual healing of the cancer disease proved abortive [4-6].

In Nigeria, the religious leaders have a strong influence on their followers. In many cases, they are being referred to as someone next to God. At times, people consult them for healing prayers, blessings, and counselling. Similarly, the seminarians who are the future religious leaders, usually occupy leadership positions in the religious institutions where they find themselves. The seminarians are also, though to a lesser extent, consulted for prayers and counselling too.

Since the religious leaders and seminarians are visited for healing prayers, it will be of importance to conduct a study to explore their opinions on the common risk factors of cancer, as the information obtained will determine their level of awareness on the evidence-based cancer aetiology and risk factors. Based on the above, we aim to write a short report on the opinions of a sample of religious leaders and seminarians in Ibadan City, Nigeria, on the most common causes of cancer in the Nigerian society.

OUR STUDY

This study was a descriptive cross-sectional study. This study also forms part of a bigger study conducted among religious leaders and seminarians in Ibadan, Nigeria [9], which adopted the use of same methodology.

However, the study tool used in this present study was a paper semi-structured questionnaire which obtained information on the socio-demographic characteristics of the participants, and the five commonest causes of cancer in the Nigerian society.

A total of 350 participants were recruited for this study. Each of the participants was given a questionnaire to fill and return. After the retrieval of the administered questionnaires, only 311 questionnaires were found filled. Out of the 311 filled questionnaires, only 9 were discarded because they were not filled properly, so we finally worked on the data from 302 respondents. Research data were entered into the SPSS version 16 software for analysis. The frequency distributions of all variables were determined, and test of association between two non-continuous variables were done using the Chi-square test. A significant p-value was recorded as <0.05 .

This study was conducted under strict compliance with the 1964 Helsinki Declaration on health research involving human subjects.

FINDINGS

The demographic characteristics of the respondents had been presented earlier in a paper by Badru and Kanmodi [9]. Table 1 depicts the opinions of the respondents on the causes of cancer in the Nigerian society. The top five cancer aetiology/risk factors, as indicated by the respondents, are as follows: toxic drugs (58.9%); genetic factors (53.6%); radiation exposure (52%); poison (42.4%) and poverty (34.8%).

Table 1. Association between gender of respondents and their opinion on the commonest cancer causes

Cancer causes	Frequency (%) [N = 302]
Sin	79 (26.2)
Evil spirit	85 (28.1)
God	17 (5.6)
Radiation exposure	157 (52.0)
Toxic drugs	178 (58.9)
Genetic factor	162 (53.6)
Generational curses	66 (21.9)
Witchcraft	58 (19.2)
Poison	128 (42.4)
Wealth	57 (18.9)
Poverty	105 (34.8)

DISCUSSION

The Nigerian religious leaders are known to have strong influence over their followers; these leaders bear different religious titles such as Pastor, Reverend, Evangelist, Imam, Alfas, among others. The pastors, evangelists, reverends, and missionaries are of the Christian faith, while the Imams and Alfas are of the Islamic faith. These religious leaders see to the social and spiritual welfare of their followers. On many occasions, they organize sessions of healing prayers for their sick followers. The seminarians, on the other hand, are trainees hoping to become a religious leader someday. As a matter of fact, some seminarians are likewise actively engaged in religious leadership positions in the Nigerian society.

This study was conducted to explore the opinions of religious leaders and seminarians in the metropolitan city of Ibadan, Nigeria, on the five most common causes of cancer in the Nigerian society. The findings made from this study revealed diverse opinions on this issue of concern, and these opinions are noteworthy. It is interesting to note that roughly one-quarter believed that sin can cause cancer disease. The Merriam-Webster Dictionary defines sin as: an offense against religious or moral law; an action that is or is felt to be highly reprehensible;

an often serious shortcoming; a transgression of the law of God; or a vitiated state of human nature in which the self is estranged from God [10]. This, by interpretation, suggests that many believed that many cancer diseases in the Nigerian society are afflictions from God.

Furthermore, the opinion of the surveyed religious leaders and seminarians on socioeconomic factors being responsible for having cancer is also insightful. Some of them believed that poverty and wealth can make one to develop cancer diseases. However, and fortunately, the evidenced-based medical risk factors of cancer (such as genetic factors, radiation exposure, poison, toxic drugs, etc.) were known by many of the respondents in this study; this shows that many of them acknowledged that cancers can be caused by biological, physical and chemical factors.

CONCLUSION

In conclusion, many of the surveyed religious leaders and seminarians were of the opinion that cancer is mainly caused by biological, physical and chemical factors; however, some of them still have the belief that socioeconomic and supernatural factors are the causes of cancers in the Nigerian society.

ACKNOWLEDGMENTS

This study was self-funded. Authors have no conflict of interest to declare. This chapter was also a revised version of an earlier publication of the authors [11].

ABSTRACT

In this chapter we try to determine the awareness rate of students in the University of Ibadan campus on restorative dental treatment and also explore their perceived needs for a dental restoration. Methods: Data of surveyed 668 University of Ibadan students was used in this study. Study tool was a well-structured self-administered questionnaire. Analysis was done using the SPSS version 16 software. Results: The majority (55.2%) of the respondents were within the age range of 21-25 years, 51.3% were females, and 76.8% were Yorubas. The majority (96.9%) were aware of a dentist, while only 34.1% had ever visited a dentist in their life time. Only 14.22% had missing teeth, 17.7% had broken teeth, while 19.5% had discolored teeth. The majority (82.3%) were aware that a missing tooth can be restored. Only 47 out of the 130 respondents who had a discolored tooth felt the need to get a dental restoration. Only 115 out of 415 respondents who had a broken tooth felt the need to get a dental restoration. Removable denture is the most popularly known (36.7%) dental restorative device among the respondents. Conclusions: This study revealed a very high awareness rate of a dentist among students of the University of Ibadan. Many of these students had defective teeth that needed restoration; however many did not perceive the need to get them restored. The authors recommend the need for education and awareness on the benefits of good oral health status.

INTRODUCTION

The teeth constitute an important part of the human body that aids in mastication, phonation, and aesthetics [1]. Deviation from the normal state of health of a tooth can result into a diseased state and pain [2-5]. This could arise from insults to the tooth [2, 3], like trauma, bacterial action, erosive chemicals, heat, among others [4, 5], causing dental diseases like tooth wear lesions, pulpitis, pulpal necrosis, periapical abscess, pain and ultimately tooth loss [2, 6].

The literature had reported a significant prevalence of dental diseases among different Nigerian populations and across different age groups and socio-economic strata [7-10]; thus making it a public health problem in Nigeria. Public awareness on oral health had also been well documented, and had been found to be increasing over the years [9-11]. Despite this gradual increase in the awareness rate on oral health in Nigeria, a high prevalence of dental disease is still seen among Nigerians [10, 12]. This has been attributed to a number of contributing factors including ignorance, anxiety of getting dental treatments, poverty, unperceived need for dental care, and extremely high population – dentist ratio [13-19].

Ignorance about the possibility of restorative treatment for a diseased tooth has been found to be high among lay people [13, 14], causing many of them to suffer intractable tooth ache, poor quality of life, and anodontia [14]. Inability to perceive and attend to dental health needs early had also been found to be low among the lay Nigerian adult populations [15], making many of them to present late at the dental clinic when their dental diseases had already developed complications requiring higher treatment costs [15]. Anxiety for dental treatment also had been well studied among different populations [16]. As a matter of fact, some dentally anxious individuals often delay visiting a dental surgery for a long period of time, causing detrimental effects on their dental health conditions which in turn make their dental treatment needs more complex due to the complications that would have arisen [16]. All these problems – ignorance, anxiety of dental treatment, and unperceived needs, are psychosocial factors that could be solved through oral health education [13, 20, 21].

The problems of the socio-economic deprived population – dentist ratio and high poverty rate in the country are demographic and economic problems that could be solved by the government [13, 22]. Research has shown that a number of fruitful efforts, over the years, had been made by the government in this regard, to reduce the intensity of these two problems [23, 24]. However, more still needs to be done in making comprehensive dental health care more accessible for the Nigerian masses [13, 22].

After thorough search of the literature, the authors observed scanty literature on the awareness of Nigerian adults on the restorative treatment options for a defective tooth, and also on their perceived need for a dental restoration [9, 25]. Also, the majority of the available studies in this area were conducted amongst the health professionals and their trainees [9, 25, 26]. To the best of the authors' knowledge, no published research data exist on the awareness rate and perceived needs of the University of Ibadan students on restorative dental treatment. This study aims to determine the level of awareness of the students on the University of Ibadan campus on restorative dental treatment and also to explore their perceived needs for a dental restoration.

OUR STUDY

This cross-sectional study was conducted in accordance with the Helsinki Declaration. Ethical clearance to carry out this study was officially obtained from the Ministry of Education, Ibadan, Nigeria. The study was conducted among students of the University of Ibadan. This tertiary institution is the premier university of the country and she is situated within the city of Ibadan, Nigeria. This school had a total of twelve [12] academic faculties (see Figure 1), with each faculty running both undergraduate and postgraduate academic program.

Keywords: A= Faculty of Veterinary Medicine; B= Faculty of Pharmacy; C= Faculty of Law; C= Faculty of Science; D= Faculty of Arts; E= Faculty of Public Health; F= Faculty of Agriculture; G= Faculty of Social Sciences; H= Faculty of Basic Medical Sciences; I= Faculty of Clinical Sciences; J= Faculty of Dentistry; K= Faculty of Technology; L= Faculty of Education; N= Faculty not indicated.

Figure 1. Faculty distribution of respondents.

The study tool for this present study was a well-structured four-sectioned pre-tested questionnaire, which was adapted from a similar study [9]. The first section obtained information on the socio-economic attributes of the participants. The second section obtained information about participants' awareness of a dental surgeon, and the possibility of restoration of a defective or missing tooth. The third section obtained information about participants' awareness of common dental restorations. The fourth section obtained information about participants' knowledge of the use of the dental restorations mentioned earlier in the third section.

Participant's selection was based on lack of exposure to clinical training in dentistry. Based on this criterion, all bona fide students of the University of Ibadan were considered eligible, except for those dental students that have started the clinical phase of their training in dentistry and the senior medical students (i.e., those medical students in the clinical phase of their study program) who had rotated through clinical postings in dentistry.

A sample of 700 students was interviewed in this study via our study tool (i.e., a self-administered questionnaire). Study participants were approached in their classrooms and dormitories. The aims and objectives of the study were clearly explained to them, and they were also informed about the confidentiality of their participation. Verbal informed consent was sought from each participant before being issued a questionnaire to fill. Only 676 participants returned their questionnaires filled, of which 8 were discarded during data cleaning process. Data collection process was done from October to December, 2014.

Data analysis was done using the SPSS version 16 software. Frequencies of variables were illustrated using tables and a chart. Tests of association between variables were done using the Chi-square test and a p-value of <0.05 was considered to be of statistical significance.

FINDINGS

Out of the 700 persons recruited for this study, only 676 responded, giving a response rate of 96.6%. Table 1 shows the socio-demographic attributes of the participants. The majority (55.2%) were within the age range of 21-25 years, 51.3% were females, 81.6% were Christians, while 76.8% were from the Yoruba tribe. Figure 1 illustrates the faculty distribution of the respondents. About one-fifth (18.9%) of our respondents were students from the Faculty of Veterinary Medicine.

Table 1. Socio-demographic attributes of respondents

Characteristics (n=668)	N	%
Age*		
16 – 20	205	30.7
21 – 25	369	55.2
26 – 30	64	9.6
31 – 35	6	0.9

Hausa	5	0.7
Others	58	8.7
Not specified	8	1.2

n=total number of respondents in this study; N= total number of respondents in each category; *Age was reported in years.

Table 2 shows the rate of awareness of the dentist and the possibility of restoration of a defective tooth among our respondents. The majority (96.9%) of them were aware of a dentist, however only 34.1% had never visited a dentist in their life time. Only 14.22% had a missing tooth, 17.7% had a broken tooth, while 19.5% had a discoloured tooth. The majority (82.3%) were aware that a missing tooth can be restored.

Table 2. Awareness of respondents about a dentist and the possibility of the restoration of a defective tooth

Variables	Yes (%)	No (%)	NR (%)
Do you know who a dentist is?	647 (96.9)	19 (2.8)	2 (0.3)
Have you ever visited a dentist before?	228 (34.1)	428 (64.1)	9 (0.13)
Have you had any restoration placed on your tooth before?	76 (11.4)	588 (88.0)	4 (0.6)
Do you have a missing tooth?	95 (14.2)	569 (85.2)	4 (0.6)
Are you aware of replacement of a missing tooth in the mouth?	550 (82.3)	111 (16.6)	7 (1.0)
Do you have a broken tooth?	118 (17.7)	547 (81.9)	3 (0.4)
Do you know if a broken tooth can be restored?	412 (61.7)	192 (28.7)	62 (9.3)
Do you have a discoloured tooth?	130 (19.5)	521 (78.0)	17 (2.5)
Do you know if a discoloured tooth can be restored?	328 (49.1)	286 (42.8)	54 (8.1)
Has anybody advised you to restore/replace a tooth before?	115 (17.2)	530 (79.3)	23 (3.4)

NR= No response.

Table 3 shows statistically significant relationships between respondents' dental problems, and perceived need for a dental restoration. Only 47 out of the 130 respondents who had a discoloured tooth felt the need to get a dental restoration (see Tables 2-3). Only 115 out of 415 respondents who had a broken tooth felt the need to get a dental restoration (see Tables 2-3.)

Table 3. Comparison between respondents' dental problems, and perceived need for a dental restoration

		Have you ever felt the need to restore/replace a tooth at any time? **			
		Yes	No	Total	p – value (X ²)
Do you have a discoloured tooth? **	Yes	47	81	128	<0.0001
	No	67	437	504	
	Total	114	518	632	
Do you have a broken tooth? **	Yes	50	68	118	<0.0001
	No	85	460	525	
	Total	115	528	643	
Do you have a missing tooth? **	Yes	45	50	95	<0.0001
	No	68	479	547	
	Total	113	529	642	

**Not all respondents gave a response to this variable, hence missing values were not computed in this statistics.

Table 4 shows the comparison between the awareness and the knowledge of respondents on the specific use of the common restorative devices. Only 245 out of the 283 respondents who had heard of a removable denture knew its use. Removable denture is the most popularly known (36.7%) dental restorative device among our respondents.

Table 4. Comparison between the awareness and knowledge of respondents on the specific use of the common dental restorative devices

Restorative devices	Awareness*			Knowledge of use*			p – value (X^2)
	Yes	No	NS	Yes	No	IDK	
Removable denture	283	301	63	245	42	360	<0.0001
Bridge	237	324	84	123	108	414	<0.0001
Crown	333	241	72	198	64	384	<0.0001

NS= Not sure; IDK= I don't know; *Missing values were not computed in this analysis.

DISCUSSION

Dental health can be described as the state of freedom from diseases affecting the teeth [27]. Whenever there is a significant insult to a tooth, dental disease sets in. Dental diseases, such as tooth loss, tooth discolouration, and pathologic tooth fracture, can negatively affect an individual's quality of life [28, 29].

Individuals with dental diseases tend to suffer from social inequalities [29]. Unfortunately, many of those with dental diseases have been found to carry these problems along with their day-to-day activities while being ignorant of the possibility of having restorations done on these defective teeth [9, 12, 14]. Furthermore, some of them suffer from speech and masticatory difficulties of varying degree of severity, depending on the stage of the dental disease progression [30-32].

A way to nib the progression of dental diseases and its complications is to seek for a professional dental care [15]. The aspect of dentistry that deals with the restoration of diseased tooth is called restorative dentistry. The various possible restorative treatment options for a diseased tooth include dental filling, crown, veneer, denture, bridge, dental implant, among others.

Quite a number of studies had been published on the awareness rate of oral health and the prevalence of perceived oral health needs among different Nigerian populations [9-11, 13-15]. However, to the best of the authors' knowledge, no published article had reported data on these subject areas amongst the population of the University of Ibadan students. The need for relevant research data on the prevalence of perceived restorative dental needs and the level of awareness of University of Ibadan students on restorative dental treatment options informed the authors to conduct this present study.

In this present study, the authors observed that the majority (96.9%) of the respondents were aware of the dentist (see Table 2). Unfortunately, many (64.1%) of them had never visited a dentist in their life time. This finding is slightly similar to that reported by Sulaiman and Kanmodi [9] in a study where they reported an awareness rate of 99.0% among some surveyed nursing students in Ibadan. In their study, they observed that the majority (78.5%) of their respondents had never visited a dentist in their life time; however this rate was higher than the one observed (64.1%) in this study. Overall, this shows that many tertiary students in Ibadan do not visit a dentist for regular dental check-ups, despite the high awareness rate of the dentist among them. Many of the respondents in this study had missing, fractured, and discoloured teeth; however not all of them have had them restored/replaced. This may be due

to many factors, some of which may include ignorance, stress of visiting a dentist, anxiety, and financial limitations [13, 14, 17, 19, 33].

Some of the respondents who had fractured teeth did not see any need to get those teeth restored. This may be due to ignorance of the possible complications associated with tooth fracture. The complications that could arise from a fractured tooth include pulpal necrosis, periapical abscess, periapical cyst, dentoalveolar abscess, tissue space infections, cavernous sinus thrombophlebitis, amongst others. This finding reveals a necessitating need to appropriately educate this population group on the socioeconomic and health benefits of seeking early treatment of a fractured tooth.

This study also showed that removable denture is the most popularly known restorative device among the respondents in this study. This finding is similar to that reported among a population of surveyed nursing students in Ibadan [9]. Authors suggest that the relatively low cost of removable dentures, amongst other restorations, may be the most likely reason why removable denture is the most popular dental restoration among this study population.

Quite a lot of the respondents in this study did not know about the use of the common types of dental restorative devices. This suggests that many of them had limited knowledge of the different restorative options they could seek for regarding their defective teeth. This calls for the need to educate them on this area.

This study has its limitations. It did not explore the reasons why some study participants had not visited a dentist in their life time. It also did not enquire into the purpose of the past dental visits of the respondents. This study surveyed a single institution; hence data of students in other tertiary institutions were not captured.

CONCLUSION

To the best of the authors' knowledge, this study is the first study that ever determined and explored awareness rate and perceived needs for restorative dental treatment amongst the University of Ibadan students, respectively. Most of the available published studies that had been conducted in this area only surveyed Nigerian health professionals and trainees [9, 25, 26]. In this study, we observed a very high awareness rate of a dentist amongst students of the University of Ibadan. Furthermore, many of them had never visited a dentist in their life time; hence they lacked adequate knowledge about their oral health status. Some of them had fractured, discoloured, and/or missing teeth that need restoration, but had not got them restored. This shows the need to educate and encourage them to get those teeth restored before complications develop from them. Educating them about this issue is very important because many of the individuals in our environment do present late to the dentist when complications had already occurred [15].

ACKNOWLEDGMENTS

This study was conceptualized by AOS and KKK. Data collection was done by AOS and KKK. Data analysis was done by BAA and KKK. Manuscript write-up was done by AOS and KKK. All authors read and approved the manuscript. Authors have no competing interest to

Chapter 367

THE ROLE OF FEAR OF MENTAL ILLNESS ON ACADEMIC PERFORMANCE OF NIGERIAN MEDICAL STUDENTS

Kehinde K. Kanmodi^{1,*}, BDS and Bello Almu², BSc, MPPA

¹Cephas Health Research Initiative Inc, Sokoto, Nigeria

²Department of Sociology, Usmanu Danfodiyo University, Sokoto, Nigeria

ABSTRACT

There is a popular belief in the Nigerian society that reading too much can result in mental illness. Interestingly, virtually no research literature had recorded any relationship between this belief and academic performance of Nigerian students. *Objectives:* To evaluate the impact of the belief that reading too much can cause mental illness on the academic performance of Nigerian students. *Study group:* The final year medical students of the Usmanu Danfodiyo University, Sokoto, Nigeria. *Methods:* A cross-section of 60 final year medical students was interviewed using a self-administered anonymous questionnaire. The questionnaire obtained information from the participants on their socio-demographic characteristics, academic records, and beliefs on reading too much to be a cause of mental illness. Data obtained were analyzed using the SPSS version 16 software. *Results:* The mean ($\pm$ SD) age of the respondents was 26.05 ($\pm$ 4.34) years, and the majority (83.3%) of them were males. Less than one-tenth (6.7%) of them reported that they had excellent performance in their current study programme. A higher proportion of the females, when compared to the males, were of the mind-set that too much reading is dangerous to the brain (6/10 (60%) versus 16/50 (32%), p -value = 0.533). Also, a higher proportion of those that did not believe that reading too much could cause mental illness had a very good to excellent academic record in their current academic program, when compared to those with such belief (12/39 (30.8%) versus 3/13 (23.1%), p -value = 0.409). *Conclusion:* Students who did not believe that they can develop mental illness as a result of reading too much generally had better academic performance than those that had such belief.

INTRODUCTION

Education is a powerful tool for the attainment and sustenance of development of any nation. For any nation to develop, her citizens need to be properly educated and well informed. More importantly, it is not sufficient for the citizens of a nation to just attend school, but getting the best from school education should be the main focus. In Nigeria, a lot of individuals are in school, however only a small fraction of them are getting the best from school education [1]. There are many factors that limit Nigerian students from getting the best from school education. Some of these factors include poverty, terrorism, and socio-cultural beliefs, among others [2-5].

If we focus on socio-cultural beliefs, we will find many factors limiting the proper utilization of educational opportunities among Nigerian students. For example, it is a popular belief in some Nigerian societies that educating a girl-child is a sheer waste of time, because a girl child is presumed to end up as a housewife when married [3]. This belief had hindered many girls from getting the best from school education [3]. From our observation, there is also a popular societal belief that reading too much can cause mental illness; this belief had made many people to embrace academic mediocrity on account of fears of developing mental illnesses that may arise from rigorous pursuit of academic prowess. After extensive literature search, we found that virtually no literature had recorded any relationship between this belief and academic performance of Nigerian students.

It will be of many benefits to the Nigerian society if the impact of the fear of developing mental illness from reading too much can be measured among Nigerian students. This study aims to evaluate the impact of this belief on the academic performance of Nigerian students, using the final year medical students in Sokoto State, Nigeria, as a case study. Conducting this kind of study among this peculiar population group (i.e., medical students) is of high significance, being that this population group is expected to be more medically knowledgeable about the medical causes of mental illness than the lay populations. Hence, the findings made from this study will give a projection of what may obtain of such among the lay populations.

OUR STUDY

This study was a cross-sectional study conducted under the guidelines of the Helsinki declaration on research involving human subjects. The study population was the medical students studying at the medical school of the Usmanu Danfodiyo University (UDU), Sokoto Metropolis, Sokoto State, Nigeria. This university (i.e., UDU) is the home to the one and only medical school in the entire Sokoto State. This school runs a six-year medical degree program. This program has two phases, which are the pre-clinical and the clinical phases; those students in the 1st, 2nd, and 3rd undergraduate years (UGYs) are in the pre-clinical phase while those in the 4th, 5th, and 6th UGYs are in the clinical phase. Those medical students that are in the clinical phase of their medical program are domiciled within the Usmanu Danfodiyo University Teaching Hospital (UDUTH), while those in the preclinical phase are domiciled within the university campuses. This hospital is a tertiary hospital affiliated to the UDU. Both the hospital and the university campuses are situated within Sokoto metropolis.

The study instrument was a well-structured questionnaire designed by the authors. The questionnaire had three sections:

- The 1st section obtained information on the socio-demographic characteristics of the participants;
- The 2nd section obtained information on the participants' beliefs regarding reading too much to be a cause of mental illness;
- And the 3rd section obtained information on the participants' academic records

Authors developed some two criteria for the participants' selection. Below are those criteria:

- Willingness to participate in the study
- Completion of clinical postings in Psychiatry

The justification for including the completion of postings in Psychiatry as part of the eligibility criteria was that Psychiatry is a medical specialty that deals with the management of mental illnesses; hence, this will ensure that all subjects are averagely knowledgeable about the causes and risk factors of mental illnesses before participating.

Based on these eligibility criteria highlighted above, only those medical students in their 6th UGY (n = 98) could participate in this study.

The eligible medical students (i.e., those in their 6th UGY) were approached at their lecture hall and dormitories. They were informed about the purpose of the study, and that their participation is strictly voluntary and confidential. Only those that gave verbal informed consent to participate in the study were given an anonymous questionnaire to fill and return. Participants' selection was done using simple random sampling technique. Out of the 65 questionnaires administered, only 60 were returned filled.

All the returned questionnaires (n = 60) were used for this study; none was discarded because they were all appropriately filled. Data was analyzed using the SPSS version 16 software. Frequency distributions of all variables were determined and Chi-square test was used to compare relationships between the qualitative variables with a p-value of <0.005 considered to be of statistical significance. The results obtained from the analysis were presented using tables and charts.

FINDINGS

The mean ($\pm$ SD) age of the respondents was 26.05 ($\pm$ 4.34) years. The majority of them were single (86.7%), and in the male gender (83.3%) category (see Table 1).

The majority (66.7%) of the respondents made a minimum of credit pass in all the 5 compulsory subjects needed to secure their admission into their current medical programme in a sitting (see Table 2). Also, less than one-tenth (6.7%) of the respondents reported that they had excellent performance in their current study programme (see Table 3).

A higher proportion of the females, when compared to the males, were of the mind-set that too much of reading is dangerous to the brain (6/10 (60%) versus 16/50 (32%), p-value =

0.533) (see figure 1). Furthermore, a higher proportion of those respondents that did not believe that reading too much is dangerous to the brain passed their O' level entrance examination to the university at one sitting when compared to those that believed the opposite (20/21 (95.2%) versus 17/23 (73.9%)) (see Table 2).

Table 1. Socio-demographic characteristics of respondents

SD = Strongly disagree; D = Disagree; U = Undecided; A = Agree; SA = Strongly agree.

Figure 1. Response of the respondents to the statement: Too much reading is dangerous to the brain.

Table 2. Comparison between the depths of belief of the respondents on “reading too much” to be dangerous to the brain with the frequency of sitting attempts for their O’ level examination

Variable	Too much reading is dangerous for the brain (n = 60)						X2
	SD	D	U	A	SA	Total	
How many times did you sit for your O’ level examination before you passed all the 5 compulsory subjects you needed to secure admission for your current study programme?	Once	6 (10.0)	14 (23.3)	3 (5.0)	14 (23.3)	3 (5.0)	0.730, df = 20
	Twice	3 (5.0)	4 (6.7)	3 (5.0)	2 (3.3)	1 (1.7)	
	Thrice	1 (1.7)	0 (0.0)	1 (1.7)	1 (1.7)	4 (6.7)	
	Four times	0 (0.0)	1 (1.7)	0 (0.0)	0 (0.0)	1 (1.7)	
	Five times	0 (0.0)	1 (1.7)	0 (0.0)	0 (0.0)	1 (1.7)	
	>5 times	1 (1.7)	0 (0.0)	0 (0.0)	0 (0.0)	1 (1.7)	
	Total	11 (18.3)	20 (33.3)	7 (11.7)	17 (28.3)	5 (8.3)	

SD = Strongly disagree; D = Disagree; U = Undecided; A = Agree; SA = Strongly agree.

Table 3. Comparison between the beliefs of the respondents on “reading too much” to be a mental illness risk factor with their academic performance

Variable	Reading too much can make me run mad (n = 60)*						X2
	SD	D	U	A	SA	Total	
So far in your current academic program, what is the rating of your academic performance?	Average	5 (83.3)	6 (10.0)	2 (3.3)	2 (3.3)	17 (28.3)	0.409, df = 12
	Good	7 (11.7)	9 (15.0)	4 (6.7)	6 (10.0)	26 (43.3)	
	Very good	6 (10.0)	3 (5.0)	0 (0.0)	2 (3.3)	11 (18.3)	
	Excellent	2 (3.3)	1 (1.7)	0 (0.0)	0 (0.0)	4 (6.7)	
	Total	20 (33.3)	19 (31.7)	6 (10.0)	10 (16.7)	58 (96.7)	

*Data of two respondents were not computed because they gave no complete response to the variables cross-tabulated.

SD = Strongly disagree; D = Disagree; U = Undecided; A = Agree; SA = Strongly agree.

Lastly, a higher proportion of those that did not believe that reading too much could cause mental illness had a very good to excellent academic record in their current academic program, when compared to those with such belief (12/39 (30.8%) versus 3/13 (23.1%), p -value = 0.409) (see Table 3).

DISCUSSION

Madness can be defined as a state of severe mental illness [6]. Mental illness can be described as a health condition involving changes in thinking, emotion or behaviour (or a combination of these) [7]. The risk factors for mental illness among school-age individuals are diverse [8]. However, some school-related risk factors that could cause mental illnesses among these individuals include adverse learning environment, difficulties at school, and lack of educational opportunities [8].

It is noteworthy that the impact of Nigerian socio-cultural beliefs on mental illness on formal education had been under-explored. For instance, and to the best of the authors' knowledge, no available study had reported the impacts of such beliefs on the academic performance of tertiary school students. The rationale for conducting this study was to explore the impact of the fear of developing mental illness as a result of reading too much.

In this study, it is alarming that despite the level of medical knowledge of the respondents on the aetiology and risk factors of mental illness, yet a significant proportion of them still believed that reading too much could cause mental illness. If this kind of belief was found to be as this common among final year medical students, how much more the medical students in lower classes as well as those students in the non-medical disciplines. Furthermore, this belief was found to tell negatively on the academic performance of those medical students that believed in such. By implication, it could be said that quite many of them had not benefitted maximally from medical education due to this belief.

In the nearest future, the respondents in this present study will hopefully graduate as a medical doctor, and start working as clinicians. Clinical practice requires continual medical education. A clinician who desires to be of relevance in the society needs to keep updating his/her medical knowledge from time to time. To be up to date in the current trends of patient management, a clinician has to passionately embrace lifetime studying. From this juncture, it is good to recall that many of the surveyed medical students believed that reading too much could make them develop mental illness. This may suggest that some of them may possibly not want to further their medical education after concluding their medical programme, due to the heavier academic workload in postgraduate studies, which will demand more intensive studying of books.

For a nation to be strong, the factors limiting the maximal utilization of her citizens on educational pursuits need to be successfully eradicated. In this study, we found out that the fear of developing mental illness from reading too much is a factor limiting the surveyed medical students from having better academic performance in their current study program. Based on this finding, it could be said further that students in other academic disciplines will most likely be experiencing similar problems, telling negatively on their academic performance likewise.

However, this study has its limitation. This study did not survey the medical students in lower classes as well as those in other Nigerian medical schools; this informs the need to conduct a bigger study on this subject matter. Also, this study did not enquire into the reasons why the respondents believed that reading too much could cause mental illness; hence, conducting a qualitative study to explore the reasons behind this belief among medical students will be of benefit. From the findings made in this research, authors would like to recommend the following:

- Proper education and counselling of medical students, as well as the entire public, on the evidence-based causes of mental illness
- A need for research to explore the degree of impact of the belief that reading too much could cause mental illness on the academic performance of Nigerian students from the secondary to the tertiary level of education
- Disabusing the minds of Nigerian youths from the beliefs that reading too much could make them develop mental illness

In conclusion, the wrong belief that reading too much is dangerous to the brain had contributed negatively to the academic performance of the surveyed Nigerian doctors-to-be. Academic diligence is not a risk factor for mental illness; rather it boosts one's memory status, and help to reduce one's risk of developing neurodegenerative diseases like Alzheimer's diseases [9]. Proper public education needs to be done on the proven risk factors of mental illness. It will also be very helpful to the Nigerian society if a survey could be conducted to assess the extent of the damage made by this popularly observed belief among Nigerian youths.

ACKNOWLEDGMENTS

This study was funded by the authors. Authors appreciate the kind assistance of Mr. Tajudeen Musbau, a medical student of the UDU, during the data collection process. Also, this chapter was a revised version of an earlier publication of the authors [10].

ABSTRACT

Hepatitis B viral infection is a killer disease that can be prevented through proper vaccination. This study aims to determine the awareness and acceptance rates of hepatitis B vaccination by pregnant women in Sokoto City, Nigeria. Methods: A cross-section of 330 pregnant women was surveyed in this study using an interviewer-administered questionnaire. The questionnaire obtained information on the demographic profile, hepatitis B vaccine awareness, vaccination status, and attitudes of the subjects towards hepatitis B vaccination. Data collected was analyzed using the SPSS version 20 software. Results: All the respondents were married, 40.3% of them were within the age range of 20 to 25 years, 74.8% had no source of income, and 38.5% had no formal education. Only 3.9% of the respondents were aware of hepatitis B vaccine, of which none of them had ever received the vaccine. However, more than 90% of the respondents would like to get the vaccine. Conclusions: The findings made from this study revealed a very low awareness rate on hepatitis B vaccine amongst pregnant women in Sokoto City, Nigeria. However, many of them would like to get vaccinated against HB infection.

INTRODUCTION

Hepatitis B (HB) viral infection is a potentially life-threatening liver infection that is chronically affecting about 370 million individuals globally; unfortunately, about 2 million people die of complications arising from the disease yearly [1]. Hepatitis B viral infection is known to be caused by the hepatitis B virus (HBV). This virus is a double stranded DNA virus which belongs to the hepadnaviridae family. The mature HBV is spherical in shape and it has 4 different genes; these genes include the HBsAg, HBcAg, HBeAg, and the nucleocapsid which encloses the viral DNA [2-4].

In Nigeria, pregnant women constitute one of the population groups that are highly predisposed to hepatitis B infection [5]. Furthermore, statistics had shown that about 14.1% of pregnant women in Nigeria are living with hepatitis B infection [5]. One of the major problems associated with hepatitis B infection among pregnant women is mother-to-child transmission (MTCT) of the virus [6]. Sadly, about 1 out of 10 Nigerian children are infected with hepatitis B, of which the majority of them acquired the infection through MTCT of the virus [5-7]. In order to eradicate MTCT of HBV in Nigeria, the Nigerian government began HB vaccination programs in the year 2004 [2, 8]; fortunately these programs are still active till date. Furthermore, impressive success rates had been recorded through these vaccination programs [9-12]. However, there are still some stumbling blocks hindering the holistic success of these vaccination programs. Some of these stumbling blocks include: low awareness rate on the disease; lack of reliable cold chain in storing the vaccine; illiteracy; limited health personnel; poverty; and ignorance [7, 13].

From our literature search, we observed that different studies have determined the awareness and acceptance rates of HB vaccination among people in different geographical areas in Nigeria [14-23]. Interestingly, the majority of those studies were found to have been conducted among health workers. However, we observed that only very scanty literatures were available on the awareness and acceptance rates of HB vaccination among pregnant women in Nigeria.

This study aims to: determine the awareness rate on HB vaccination; determine the acceptance rate of HB vaccination; and also explore the factors that might have influenced the choice of pregnant women in Sokoto City, northwestern Nigeria, on accepting hepatitis B vaccine. This study is of high significance, as the study will provide the first literature exploring the factors influencing the choice of acceptance of HB vaccine among pregnant women in Sokoto City, northwestern Nigeria.

OUR STUDY

This study was a cross-sectional survey of pregnant women attending the antenatal clinics of two public hospitals situated within Sokoto City, Nigeria. The names of the two surveyed hospitals were: Maryam Abacha Women and Children Hospital; and Specialist Hospital. These hospitals are owned by the Sokoto State Government, Sokoto State, Nigeria.

This study was done in accordance with the Helsinki Declaration on health research involving human subjects. Approval to conduct the study was officially obtained from the State Health Research Ethics Committee, Ministry of Health, Sokoto State, Nigeria (Ref. No:

SKHREC/081/017). Permission to collect research data was also sought from the management of the participating hospitals. The identity of the study subjects were kept with strict confidentiality, during and after the study. The subjects were also given the right to decline participating in the study at any stage should they find it uncomfortable to continue. Only those that gave informed consents were recruited for the study.

The study tool was a 14-item paper questionnaire developed through literature review [24-26]. The questionnaire obtained information on the demographic profile, hepatitis B vaccine awareness, vaccination status, and attitudes of each subjects toward hepatitis B vaccination. Before the above information was obtained from the subjects, the subjects were first informed about the meaning of hepatitis B in lay man terms. Also, the questionnaire was first drafted in English before being translated into Hausa: the most widely spoken local language in the study area. The translation was done by an experienced translator who is a native speaker of Hausa. The questionnaire was then back-translated into English by another translator and comparison was made for similarity, of which was found satisfactory. The questionnaire was then pretested and all necessary adjustments were made in the questionnaire to suit the purpose of the study.

The minimum sample size for this study ($n=280$) was determined using the Leslie formula for study population $<10,000$ at a HBV awareness rate of 24% derived from a previous study conducted among pregnant women in Punjab, Pakistan [24].

Within the month of December, 2017, a total of 340 pregnant women attending the antenatal clinics of the above-mentioned hospitals were approached and invited to participate in the study; only 330 women gave their consent to participate. All subjects' data were collected with the questionnaire, via face-to-face interviews. Data was analyzed using the SPSS version 20 software. The frequency distribution of all variables were determine, and comparisons between variables were done using the Chi-square test with a p-value of <0.05 set to be the level of statistical significance. Results obtained were presented using tables.

FINDINGS

Response rate was 97.1% (330/340). Four-tenth (40.3%) of the respondents were within the age range of 20 to 25 years, 44.2% had been pregnant for 1 to 3 times (aside their current pregnancy as of the time of the interview), and all (100.0%) were married. Furthermore, about two-fifth (38.5%) of the respondents had no formal education, 74.8% had no source of income, and 68.5% were married in a monogamous setting (see Table 1).

Only 3.9% of the respondents were aware of the hepatitis B vaccine. From comparisons between educational levels and awareness of respondents on the vaccine, we found that the majority (61.5%) of those that were aware of the vaccine had tertiary school education ($p\text{-value}<0.0001$) (see Table 2). None of the respondents had ever been vaccinated against HBV (see Table 3).

Table 4 provides information on the attitudes of the respondents towards HB vaccination. The majority (94.8%) of the respondents had never been vaccinated against HB infection due to unawareness. However, more than 90% of them reported that: they would like to get the vaccine; and their husband would allow them to get vaccinated against the disease. Interestingly, the cost of HB vaccine was found to be a factor limiting the majority (63.0%) of the respondents in enrolling for HB vaccination.

N=Total number of respondents in each category; X²=Chi square; df=Degree of freedom; ***No statistics were computed because "HAVE YOU EVER BEEN VACCINATED AGAINST HEPATITIS B BEFORE" was a constant.

Table 4. Attitudes of respondents toward hepatitis B vaccination

Question	Response	Frequency (%)
Why have you not been vaccinated against HBV?	Unaware that hepatitis B vaccine exist	313 (94.8)
	Unaware that the vaccine was important	14 (4.2)
	Do not believe that the vaccine is effective	1 (0.3)
	Do not believe that the vaccine is safe	1 (0.3)
	Religion does not permit vaccination	1 (0.3)
Would your husband allow you to be vaccinated against hepatitis B infection?	Yes	308 (93.3)
	No	18 (5.5)
	Not sure	4 (1.2)
Would the cost of the vaccine be a determinant to you been vaccinated?	Yes	208 (63.0)
	No	122 (37.0)
Do you like to be vaccinated against hepatitis B infection?	Yes	322 (97.6)
	No	5 (1.5)
	Not sure	3 (0.9)
Assuming you have hepatitis B infection, would you still allow your baby to receive anti-HBV antibodies?	Yes	325 (98.5)
	No	4 (1.2)
	Not sure	1 (0.3)
Assuming you are diagnosed to have HBV infection, would you be willing to take the drugs, which are safe, given to you by your doctor in order to prevent HBV transmission to your baby?	Yes	325 (98.5)
	No	3 (0.9)
	Not sure	2 (0.6)

HBV=Hepatitis B virus.

DISCUSSION

With the findings made in this study, it is glaring that the Nigerian government still has a long way to go for her to achieve her set goals of eradicating MTCT of HBV in Nigeria. In this study, a very low (3.9%) awareness rate on hepatitis B vaccine was recorded among the pregnant women that took part in the questionnaire; this rate is much more lower than that reported among pregnant women in other international cities [24, 26]. Also, none of the respondents in this present study had ever received HB vaccination. This reveals that all of the respondents are at risk of getting infected with HB if exposed to the virus. For those among them who might have been already infected with the virus, their babies stand at high risk of contracting the viral infection through MTCT.

Interestingly, only very few respondents were aware of the HB vaccine, and none of these few had got themselves vaccinated against HBV. The reasons for non-vaccination were: vaccination against the virus was not important; the safety profile of the vaccine could not be guaranteed; and the efficacy of the vaccine could not be guaranteed. Hence, it could be assumed that some of them had been misinformed about the importance of HB vaccination.

Aside the above-mentioned factors (such as unawareness, fear of safety of HB vaccine, and doubt of efficacy of HB vaccine) hindering the respondents from getting vaccinated against HBV, objection of spouses towards enrollment for HB vaccination, religious beliefs, lack of personal income, as well as the cost of the vaccine were also considerable limiting factors.

Based on our findings, many of the respondents in this study were at high risk of contracting hepatitis B infection. This observation was made based on the socio-demographic attributes of the respondents, as many of them fell into the categories of those that were:

illiterate; married in a polygamous setting; and multiparous are at risk of contracting hepatitis B infection [6]. However, many of them demonstrated positive attitudes toward receiving the HB vaccine. In fact, many of them would like to get their baby protected against HB viral infection, to the extent that they are ready to allow their baby take anti-HBV antibodies and/or also take drugs, themselves, to prevent the transmission of HBV to their baby, if infected with HBV. This shows that the respondents were very receptive to getting vaccinated against HBV.

However, this study has its limitations. First of all, this study did not objectively determine the HB sero-positivity and vaccination status of the respondents. Secondly, this study is a hospital-based study; only those that presented at the antenatal clinics of the surveyed public hospitals were recruited for the study. Based on the limitations and findings made in this study, authors would like to suggest the following:

- Conduction of a big community-based study among pregnant women in the various communities situated within Sokoto City, Nigeria. This kind of study will be able to cover the population of women who do not visit antenatal clinics during pregnancy.
- Proper education of pregnant women and their spouses on MTCT of HBV as well as the benefits of HB vaccination.
- More efforts need to be put by local and international governmental and non-governmental in supporting the HBV vaccination programs in Nigeria, so that Nigeria can achieve her set goal of eradicating MTCT of HBV.

CONCLUSION

The findings made from this study had established that there is a very low awareness rate on hepatitis B vaccine amongst pregnant women in Sokoto City, Nigeria; however, many of them would be glad to get themselves and their babies protected against HB infection through the vaccine.

ACKNOWLEDGMENTS

Authors have no competing interest to declare. This study was self-funded. Also, this chapter was a revised version of an earlier publication of the authors [27].

ABSTRACT

Shisha smoking is a known risk factor for head and neck cancer (HNC). Objectives: To determine the rate of shisha smoking among secondary school students in Ibokun Town, Nigeria. Methods: This was a pilot questionnaire-based study conducted among

* Corresponding Author's Email: kanmodikehinde@yahoo.com.

grades 7 to 12 students in two secondary schools in Ibokun Town, Nigeria. Questionnaire obtained information from the subjects on their biodata, history of shisha smoking, awareness of HNC, and attitudes toward receiving HNC education. Results: More than half (54.0%) of the subjects were ≤ 14 years old, 56.6% of them were females, 97.5% were Yorubas, 50.5% were in a private school, and 82.8% were in grades 10 to 12. Only 11 (5.6%) subjects had ever smoked shisha, and 54.5% (6/11) of them were females. Only 3, out of these 11 subjects, smoked shisha for the first time at the age of 10 years or younger. Also, 7 subjects (5 females, and 2 males) reported that they smoked shisha on all the 30 days prior to their participation in the study. Lastly, less than half (47.5%) of the subjects had never heard of HNC; however, the majority (81.8%) of them showed interest in being educated on HNC. Conclusion: This study recorded a low prevalence rate of shisha smoking among the surveyed students. Many of the subjects had never heard of HNC before; however majority of them loved to be educated on HNC. Authors recommend early HNC education for secondary school students, with emphasis placed on tobacco cessation.

INTRODUCTION

Shisha smoking, according to the British Heart Foundation, is a way of smoking tobacco, sometimes mixed with fruit or molasses sugar, through a bowl hose or tube [1]. Shisha smoking is also called hookah, narghile, waterpipe, or hubble bubble smoking [1, 2]. Shisha smoking took its history from Asia [1, 2]. In some parts of the world, shisha smoking has surpassed cigarette smoking, with its rate of use increasingly growing among children and young adults [1, 2, 3].

According to the World Health Organization, shisha smoking is an addictive behavior [2], and it has been reported that shisha smokers do take shisha in the company of relatives and friends [4-7]. This reflects that shisha smoking is an acceptable social behavior in many societies.

Unlike cigarettes where their packs have warning labels about the negative health implications associated with tobacco smoking, shisha bottles do not have such warning labels [8]. Shisha has tobacco as part of its constituents; hence shisha smoking is a risk factor for life-threatening diseases like cancer [2, 8]. Furthermore, most of the anti-smoking policies in different nations of the world are focused on cigarette, while policies discouraging shisha smoking were not in focus [9-12]. As a matter of fact, virtually no shisha-specific policy exists in many nations [2, 11, 12]. In many developed countries for instance, shisha smoking venues and shisha products are exempted from tobacco control policies [9, 10].

In Nigeria, shisha is gaining its popularity and more shisha smoking venues are erected in some Nigerian discos and restaurants [2, 13]. Interestingly, little or no empirical study is available on shisha smoking in Nigeria [13]. This preliminary study aims to determine the prevalence of shisha smoking and also explore the awareness of head and neck cancer (HNC) among a pilot sample of school-going adolescents and young adults in Ibokun Town, Nigeria.

OUR STUDY

This preliminary study forms part of the research projects conducted during the 2016 Campaign for Head and Neck Cancer Education (CHANCE) Program [14, 15]. This program was an initiative of the Cephas Health Research Initiative Inc., a non-profit indigenous non-governmental organization based in Nigeria. Permission to conduct this study was officially obtained from the authorities of the participating schools, and all subjects' participation was completely voluntary and anonymous.

Two conveniently selected secondary schools were surveyed in this study: one public school and one private school. Being a preliminary study, authors used a convenient sample of 198 students. Multistage sampling technique was used in the selection of the participating classes, while simple random sampling technique was used in the selection of the subjects from the participating classes. Prior to questionnaire administration, authors approached the students and the teachers of the selected classes in their respective classrooms; they were informed about the purpose of the study and that their participation is voluntary and confidential. Informed consent was also obtained from all that took part in the study. All questionnaires were self-administered. The questionnaire obtained information from each participant about their demographic profile, history of smoking shisha, and awareness of tobacco as a risk factor for head and neck cancer.

The collected data were cross-checked and none was discarded because they all were appropriately filled. Data was analyzed using the SPSS version 16 Software. The outcomes of the analysis were presented in tables.

FINDINGS

More than half (54.0%) of the subjects were ≤ 14 years old, 56.6% of them were females, 97.5% were Yorubas, 50.5% were in a private school, 82.8% were in grades 10 to 12, and 74.2% were Christians (see Table 1).

Only 11 (5.6%) subjects had ever smoked shisha, of which 54.5% (6/11) of them were females (see Table 2). Only 3, out of these 11 subjects, smoked shisha for the first time at the age of 10 years or younger (see Table 3). Also, 7 subjects (5 females, and 2 males) reported that they smoked shisha on all the 30 days prior to their participation in the study (see Table 4). Lastly, less than half (47.5%) of the subjects had never heard of HNC (see Table 5); however, the majority (81.8%) of them showed interest in being educated on HNC (See Table 6).

DISCUSSION

This study surveyed a pilot sample of 198 secondary school students in Ibokun Town, Nigeria, on the prevalence of shisha smoking and awareness of HNC. In this study, we observed a very low prevalence of shisha smoking among the study subjects. Also, we found that many of the subjects had never heard of HNC and the majority of them would like to be educated on the killer disease.

Not sure	11 (5.6)
No response	10 (5.1)
Total	198 (100.0)

Shisha smoking is an addictive behavior, also its smokes has detrimental effects on the body [2, 8]. The likelihood of developing smoking habit have been reported to be very high among adolescents due to some influencing factors like peer influence, parental smoking, and poor academic performance [2, 16, 17]. The age at which smoking habit is developed goes a long way in predicting an individual’s level of risk of developing tobacco-associated chronic

diseases; individuals with early exposure to tobacco smoking tends to have higher risk of developing such health problems when compared to those who started smoking at latter ages [18-21]. It is worthy of note that some of the subjects in this study experimented shisha smoking at age 10 or younger. This suggests that some of the subjects are at risk of developing tobacco-associated chronic diseases if they continue to smoke shisha.

Table 3. Comparison between gender of subjects and age at first waterpipe (shisha) smoking experience

	Response	Gender		Total	X ² (p-value)
		Female	Male		
How old were you when you first tried smoking waterpipe (shisha)?	I have never smoked water-pipe	104	76	180	0.422

No	83 (41.9)
Not sure	11 (5.6)
No response	10 (5.1)
Total	198 (100.0)

Table 6. Response of subjects to the question: Do you like to receive a comprehensive education on how to prevent head and neck cancer in future?

Response	Frequency (%)
Yes	162 (81.8)
No	30 (15.2)
No response	6 (3.0)
Total	198 (100.0)

In this study, the lifetime prevalence of shisha use among the subjects was 5.6%. Furthermore, some few subjects were found to be active shisha smokers. Some of these few subjects smoked shisha in all the recent 30 days prior to the day of participation in the questionnaire. However, the prevalence rate of shisha smoking recorded among the subjects in this present study is very low when compared to that recorded among Pakistani and German adolescents [22, 23]. The low prevalence rate recorded in this study may be because of the setting where this study was conducted, as the study area was a semi-urban area unlike the other studies which were conducted in a more developed setting.

Furthermore, we observed that the majority of the subjects had never heard of HNC. Head and neck cancer is a notorious disease which claims 300,000 lives every year [24]; hence the need for public education on its risk factors, symptoms, and HNC self-examination. In this study, the majority of the subjects showed interest in getting a comprehensive education on HNC prevention. Based on their level of motivation, authors predict that the surveyed students will benefit immensely from HNC education.

However, this study has its limitations. First of all, this study can only give an estimated prevalence rate of shisha smoking among the surveyed students, because it is difficult to ascertain if all information provided by the subjects was true. Secondly, this study did not explore how and why some subjects are active shisha smokers. Hence, there is a need for qualitative study, preferably a mixed study, to explore shisha smoking habits among secondary school students in this study area. Also, this study was a preliminary survey with small sample size; authors recommend that bigger studies should be conducted on shisha smoking in Nigeria.

CONCLUSION

To the best of authors' knowledge, this is the first study to report shisha smoking among Nigerian adolescents. This study recorded a low prevalence rate of shisha smoking among the surveyed secondary school students in Ibokun Town. Many of the subjects had never heard of HNC before; however majority of them loved to be educated on HNC. Authors recommend that such programs should be conducted for the secondary school students in Ibokun Town.

ACKNOWLEDGMENTS

Authors appreciate the authorities of the participating schools for approving the study. Authors also appreciate the teachers and students for their conduct during the study. This study forms part of the 2016 CHANCE Program of the Cephas Health Research Initiative Inc, Nigeria. Authors did not receive any external funding for this research project, and they have no competing interest to declare. Lastly, this chapter was a revised version of an earlier publication of the authors [25].

ABSTRACT

In this chapter we investigate healthcare providers' attitudes towards persons with disabilities (PWDs) at the University College Hospital (UCH), Ibadan, Nigeria. The investigators utilised the Interaction with Disabled Persons (IDP) Scale to measure the attitudes of direct and indirect healthcare providers at UCH. In all, 203 workers fully completed a questionnaire containing demographic and experiential questions and the IDP. Scores on three scale factors were analysed. The mean Discomfort score was lower for direct- versus indirect-care providers ($t=-2.537$; $p=0.012$). A higher Discomfort score was associated with a lower level of confidence in treating PWDs ($r=-0.221$; $p=0.003$). Similarly, a higher Information score was associated with lower confidence ($r=-0.300$; $p<0.001$), a lower level of training on treating PWDs ($r=-0.170$; $p=0.018$), and a lower knowledge of legislation and policies pertaining to PWDs ($r=-0.180$; $p=0.013$). The mean cubed Vulnerability score was lower for healthcare providers reporting less confidence ($t=-2.201$; $p=0.029$) and higher for older providers ($t=2.073$; $p=0.039$). Three-quarters of participants were direct-care providers, which is suggestive of physicians' willingness to deliver services to specialised populations. Recommendations are made to increase providers' confidence through in-service training, and to facilitate direct and indirect healthcare providers' organisational and individual capacities to sustain quality healthcare for PWDs.

INTRODUCTION

In numerous countries throughout the world, some factors have been identified in healthcare providers' attitudes towards persons with disabilities (PWDs). These factors, inter alia, include lack of disability-specific knowledge, discomfort with working with PWDs, fear of disability and misperceptions about disability [1-6]. These challenges are so pervasive that PWDs themselves have cited poor attitudes of physicians as the most formidable obstacle to accessing healthcare services [7, 8]. For the purpose of this study, we define attitudes as positive or negative dispositions towards a person, concept or situation. Our conviction is that a healthcare provider's attitude towards a patient is fundamental because existing misconceptions can potentially hinder diagnosis and treatment [9, 10].

Furthermore, a provider's disposition is particularly important when tending to patients with disabilities. This is because the healthcare professional may view an individual's disability as a negative trait, and such perception may prevent resources from effective utilizations [6, 11]. The assumption that a person with a disability has a baseline quality of life at a low threshold may lead the provider to avoid caring for the patient. Thus, adverse outcomes may be compounded and services available to patients may be limited if these subtle attitudes unduly affect the provider's actions.

PRIOR RESEARCH IN NIGERIA

A Nigerian study [3] found that more than half of 134 sampled healthcare workers noted that facilities and legislation related to the human rights of children with developmental disabilities are nonexistent in the country. In order to ameliorate the situation, the researchers advocated for inclusion of topics on developmental disorders in the curricula of nurses and allied medical practitioners.

Ayanniyi et al. [2] explored the knowledge and attitudes of 330 physiotherapists towards people with leprosy in the six geopolitical regions of Nigeria. The leprologists found that a significant number of participants exhibited fair knowledge, but poor attitudes towards leprosy. According to the investigators, the institution of training seems to influence the respondents' knowledge and attitudes. They advocated that educational and training programmes on leprosy should be emphasised at the basic training institutions for physiotherapists. Earlier, Awofeso [12] investigated the knowledge of nurses regarding leprosy, and reported that these healthcare workers not only lacked disability-specific knowledge, but also had a fear of leprosy. As a way of combatting such apprehensions, the author recommended that leprosy information be infused into the basic nursing curriculum in order to heighten awareness and minimise the stigma of leprosy throughout Nigeria.

Reis et al. [13], in the first population-based assessment of discrimination against people living with HIV/AIDS in four states in Nigeria, found that nine percent of professionals reported avoiding to care for an HIV/AIDS patient, and nine percent indicated that they had refused an HIV/AIDS patient admission to a hospital. Twelve percent of participants agreed that treatment of opportunistic infections in HIV/AIDS patients depletes resources, and eight percent indicated that treating an individual with HIV/AIDS is a waste of valuable resources. The researchers concluded that while most of the healthcare professionals reported being in

compliance with ethical obligations, despite the lack of resources, discriminatory behaviour and attitudes towards patients with HIV/AIDS prevail among a significant number of healthcare professionals. They identified inadequate education and absence of treatment materials as contributing to these negative practices and attitudes.

NEED FOR CURRENT STUDY

The issues discussed in the preceding paragraphs attest to the need to investigate further healthcare professionals' attitudes towards PWDs in Nigeria. Nigeria is the most populous and ethnically diverse African country, comprising 182 million people [14]. Using the World Health Organisation [15] disability threshold of 15% to determine the number of PWDs in the population, Nigeria now has 27,300,000 PWDs. This figure is expected to rise significantly in the future, given the increase in the causal factors of disabilities such as illnesses, road accidents, birth defects, collapsed buildings, poverty, environmental toxins, natural disasters, communal and religious conflict, lead poisoning, Boko Haram insurgency, and superstitions [16]. These complex variables point to the need for each country to evaluate its own attitudes towards PWDs, since these factors are powerful, yet invisible obstacles to rehabilitation and integration. The current research was therefore conceived as a way to assess healthcare providers' dispositions towards their patients with disabilities in the country.

OUR STUDY

University College Hospital (UCH), the setting for this investigation, is strategically located in Ibadan, the largest city in West Africa. Established in 1959 as a teaching hospital to service the College of Medicine, it now has over 1,000 beds, with current occupancy rates of 55-60%, and includes 60 service and clinical departments. UCH is primarily a tertiary institution with appendages of community-based outreach. Given its location in a major urban centre and its dominant role in the country, UCH caters annually to thousands of patients with varying disabilities [17].

PROCEDURES

The research protocol was approved by the Institutional Review Boards of Missouri State University, United States and the College of Medicine, Ibadan, Nigeria. Having secured approval from the two institutions, the second author distributed a total of 500 questionnaires (described below) to workers in the hospital's 20 clinics. The distribution of the questionnaires occurred during the last quarter of 2015, and the first quarter of 2016 at monthly departmental meetings.

Two hundred and fifty completed questionnaires were returned to the secretary in the office of the second author. Thereafter, the second author mailed all completed questionnaires to the first author in the United States for data entry. All data were entered into an excel

spreadsheet and imported to SPSS for analysis. In all, 203 questionnaires were found to be complete and analyzable.

Study Questionnaire

The questionnaire was prefaced by a cover letter to the participants explaining the purpose of the study and defining key terms. Disability was defined as "... an impairment in body functions that imposes limitations in activity or restricts how an individual participates in the society." Categories of disabilities were described to include those who experience orthopedic, intellectual (mental), seeing, hearing, emotional/behavioural, speaking, breathing, and other problems, including birth defects, genetic disorders and skeletal deformities. Participants were assured of confidentiality of all responses in accordance with the ethical guidelines of the two approving universities.

The questionnaire was delineated into three sections. Section one addressed basic participants' demographics, including age, gender, job title, education, and time in present position at UCH, along with experiential questions, including level of prior contact with PWDs, level of training on treating PWDs, level of confidence in treating PWDs, and knowledge of policies and legislation pertaining to PWDs in Nigeria. The second section comprised the 20-item IDP Scale developed by Gething [18]. The final section of the questionnaire was open-ended, and enabled the participants to share personalised comments.

Interaction with Disabled Persons (IDP) Scale

In her 1994 paper summarising the development and validation of the IDP since its origins in 1980, Gething [19] provides the following operational definition: "The Interaction with Disabled Persons (IDP) Scale measures attitudes in terms of level of discomfort reported by nondisabled people during interaction with people with disabilities" [19]. It consists of a 6-point Likert-type response scale ranging from "I agree very much," to "I disagree very much." Representative items include: "I admire the ability of a person with a disability to cope," and "It is rewarding when I am able to help a person with a disability." Individual items are scored from six for high agreement to one for high disagreement, with the exception of items 10, 14, and 15, which are intentionally reversed. A total score is computed by summing the item scores, excluding item 19, per Gething's instructions [18]. A higher score is interpreted as indicating a greater degree of social discomfort in interacting with PWDs.

Gething [19] confirmed a six-factor model derived from the IDP Scale. These factors and their associated proportion of the total variance are as follows: Discomfort in Social Interaction (23.3%); Coping/Succumbing Framework (12.3%); Perceived Level of Information (6.1%); Vulnerability-1st (6.0%); Coping (5.2%); and Vulnerability-2nd (5.0%).

Statistical Methods

Statistical analyses were conducted using IBM SPSS Statistics version 24. Scale and sub-scale reliabilities were assessed using Cronbach's alpha, corrected item-to-total correlations,

and inter-item correlations. A cubic transformation was applied to one factor based on Tukey's Ladder of Transformation [20] to rectify a negative skew. The correlations between ordinal-level demographic and experiential variables and factor scores were assessed with Spearman's rank correlation coefficient. The differences in mean factor scores between 2-class demographic variables were assessed using the Student's *t* test for independent samples and Levene's test for equality of variances. For 3- or 4-level demographic or experiential variables, the overall differences in mean factor scores were assessed using the F-test from a one-way analysis of variance (ANOVA) and Levene's test for homogeneity of variances. Inter-class mean differences were further assessed using the Scheffe test for simultaneous pairwise joint comparisons, with a simultaneous type I error of 5%.

FINDINGS

Table 1 summarizes the characteristics of the study participants. Relatively small response categories were combined with adjacent categories as appropriate for this table. Two-thirds of the participants were female, and their ages ranged from 18 to 60 years. Half of participants had been in their current position from 1 to 5 years. Based on their stated job title, participants were classified as either direct- or indirect- care providers (see footnote for Table 1). Nearly 80 percent of participants were engaged in direct-care, based on this classification. Over half of participants stated that they had either daily or weekly contact with PWDs. While only 11 percent reported having received at least 40 hours of training on treating PWDs, 31 percent of participants reported having either a high or very high level of confidence in treating PWDs. One-third of participants reported that their knowledge of legislation pertaining to PWDs was either none or poor.

Table 1. Characteristics of study participants

Interactions with Disabled Persons (IDP) Scale

A reliability analysis was performed using items comprising the total IDP Scale and coded following instructions by Gething [18, 19]. Additional reliability analyses were performed using the items comprising each of the six factors identified by Gething [19]. Reliability analysis for the total IDP Scale yielded a Cronbach's alpha of 0.614. It was observed that many of the corrected item-to-total correlations were very small (<0.3), and many of the inter-item correlations were negative. These observations suggest that the total IDP Scale does not form a reliable indicator for this study population. Reliability analyses for the second, fourth, and fifth factors were similarly problematic and yielded very low Cronbach's alphas of 0.180, 0.264, and 0.246, respectively. Therefore, only three factor scores were computed and retained for further analysis. Characteristics of these three factors: Discomfort in social interaction, perceived level of information and vulnerability are shown in Table 2.

Table 2. Characteristics of selected IDP scale factors

Factor	N	# items	Range	Mean	Standard deviation	Cronbach's alpha
Discomfort ^a	184	6	6-30	16.15	5.54	0.70
Information ^b	195	5	5-25	13.67	4.28	0.57
Vulnerability ^c	200	2	2-12	9.65	1.91	0.57

^a Includes items 9, 11, 12, 16, 17, and 18

^b Includes items 3, 6, 9, 10 (reversed), and 12

^c Includes items 4 and 5; this is Gething's second Vulnerability factor

Abbreviations: IDP Interaction with Disabled Persons.

A histogram of vulnerability scores revealed a moderately negatively skewed distribution. A cubic transformation was applied following Tukey [20]. The univariate distribution of the cubed factor value was more symmetrical and depicted no outliers.

IDP Factors by Participant Characteristics

A Spearman rank correlation coefficient was computed for each combination of the three IDP factors and each ordinal or interval level participant characteristic. These results are displayed in Table 3. Discomfort was significantly negatively correlated with the level of confidence in treating PWDs ($r = -0.221$). Information was negatively correlated with level of training on treating PWDs ($r = -0.170$), confidence ($r = -0.300$), and knowledge of legislation and policies pertaining to PWDs ($r = -0.180$).

Table 3. Spearman Rank correlation coefficients for selected IDP factors by study participants' characteristics

	Discomfort	Information	Vulnerability
Age (years)	-0.065 (0.389)	-0.139 (0.056)	0.136 (0.058)
Time in present position	0.034 (0.646)	-0.033 (0.651)	0.003 (0.969)
Prior contact with PWDs	-0.077 (0.303)	0.005 (0.948)	0.056 (0.434)
Training on treating PWDs	-0.090 (0.225)	-0.170 (0.018)	0.033 (0.649)
Confidence in treating PWDs	-0.221 (0.003)	-0.300 (<0.001)	-0.028 (0.693)
Knowledge of legislation and policies pertaining to PWDs	0.007 (0.928)	-0.180 (0.013)	0.006 (0.935)

Data expressed as r (p).

Abbreviations: IDP Interaction with Disabled Persons; PWDs persons with disabilities.

The differences in mean scores for each of the three factors by gender and direct/indirect care provider were assessed using the t-test. For all other participant characteristics, relatively small response categories were combined with adjacent categories as appropriate to form three classes. These classes are the same as those shown in Table 1. The presence of an overall difference in mean scores by characteristics with three classes was examined for each of the three factors and was assessed by the F-test from one-way ANOVA. Inter-class mean score differences were measured using the Scheffe test.

The first factor "discomfort in social interaction" differed significantly by classes of two characteristics. The t-test statistic for direct/indirect care provider was -2.537 (176 degrees of freedom-df; $p = 0.012$). The mean (standard deviation-sd) discomfort score was 15.57 (5.22) for direct- versus 18.05 (5.64) for indirect-care providers. The F-test statistic for level of confidence in treating PWDs was 4.964 (2, 81 df; $p = 0.008$). The mean (sd) discomfort scores for very low/low, average, and high/very high level of confidence were 19.05 (5.64), 16.31 (5.32), and 14.70 (5.55), respectively. This association was negative and nearly linear. The mean difference between classes very low/low and high/very high was statistically significant ($p = 0.009$).

The second factor "perceived level of information" differed significantly by classes of two characteristics. The F-test statistic for level of confidence was 10.994 (2, 192 df; $p < 0.001$). The mean (sd) Information scores were 16.28 (3.52), 14.00 (4.20) and 11.90 (4.05) for very low/low, average, and high/very high level of confidence. This association was again

negative and linear. The mean differences between classes very low/low and average, very low/low and high/very high, and average and high/very high were all statistically significant ($p=0.043$; $p<0.001$; and $p=0.007$, respectively).

Similarly, the F-test for level of training on treating PWDs was statistically significant ($F=4.557$; 2, 190 df; $p=0.012$). The mean (sd) Information scores for none, some, and high level of training were 14.24 (3.96), 13.84 (4.42), and 11.10 (3.87), respectively. This association was negative, but not linear. The mean differences between classes none and high and some and high were statistically significant ($p=0.014$ and $p=0.026$, respectively). The F-test for a third characteristic, knowledge of legislation and policies about PWDs, approached the 0.05 level of significance ($F=2.828$; 2, 189 df; $p=0.062$). The mean (sd) Information scores were 14.57 (4.12), 13.40 (4.23), and 12.65 (4.44) for none/poor, average, and good/very good knowledge. This association was negative and nearly linear. The mean differences between classes were not significant at the 0.05 level.

The re-expressed third factor “vulnerability” differed significantly by level of confidence ($F=3.049$; 2, 197 df; $p=0.050$). The mean (sd) cubed vulnerability scores for very low/low, average, and high/very high level of confidence were 1178 (443), 942 (424), and 1021 (479), respectively. The mean vulnerability score was higher among healthcare providers who reported very low or low confidence in treating PWDs than for providers reporting a higher level of confidence. However, the mean differences between classes were not significant at the 0.05 level. The classes were recombined to compare very low/low versus average/high/very high means; a t-test was computed and was statistically significant ($t=-2.201$, 198 df, $p=0.029$).

The F-test for age group was marginally significant ($F=2.363$; 2, 191 df; $p=0.097$). The mean (sd) cubed Vulnerability scores were 991 (414), 942 (466), and 1124 (442) for age groups 18-33, 34-43, and 44-60, respectively. The mean vulnerability score was higher among the oldest healthcare providers (ages 44-60 years) than for younger providers. The mean differences between classes were not significant at the 0.05 level. The classes were recombined to compare age 18-43 versus 44-60 means; a t-test was computed and was statistically significant ($t=2.073$, 192 df, $p=0.039$).

In order to better explain the finding of a lower mean Discomfort score for workers classified as direct- versus indirect-care providers, the distributions of other participant characteristics were examined by direct/indirect care status. Direct care providers did not differ from indirect care workers by gender, age, prior contact, or knowledge of legislation/policies. However, direct-care providers had lower representation in the mid-range [6-10] of years in current position at UCH (Chi-square =7.912, 2 df, $p=0.019$), were more likely to report having had a high (at least 40 hours) level of training on treating PWDs (Chi-square =12.437, 2 df, $p=0.002$), and were less likely to report a very low or low level of confidence in treating PWDs (Chi-square =13.359, 2 df, $p=0.001$) as compared to indirect - care providers.

Similarly, the finding of a higher mean vulnerability score for the oldest healthcare workers (44-60) versus younger workers was explored further by examining the distributions of other participant characteristics by two age groups (18-43 versus 44-60). Older workers did not differ from younger workers by direct/indirect care status, training, confidence, or knowledge of legislation/policies. Older workers were more likely to be female (Chi-square =4.849, 1 df, $p=0.028$) and had lower representation in the weekly contact class for level of prior contact with PWDs (Chi-square =8.507, 3 df, $p=0.037$) as compared to younger

workers. As expected intuitively, older workers were more likely to have been employed in their current position in the highest class of 11 or more years (Chi-square =81.803, 2 df, $p<0.001$) than younger workers.

DISCUSSION

In this study, healthcare workers in direct patient care positions had lower scores, on average, on the IDP factor Discomfort in Social Interactions with PWDs as compared to workers whose positions connote indirect care. We found a significant negative correspondence between the IDP factor Discomfort and confidence in treating PWDs, and between the IDP factor Information and confidence, level of training on treating PWDs, and knowledge of legislation pertaining to PWDs. Additionally, workers reporting a lower level of confidence had higher scores, on average, on the IDP factor Vulnerability-2nd than their colleagues reporting more confidence, and likewise for older versus younger workers.

The findings noted above are similar to results obtained elsewhere [1, 4, 21, 22]. In California, McNeal and colleagues [4] found that majority of primary care physicians have at least some difficulty in examining patients with physical disabilities and many are uncomfortable in managing their care. Similarly, a Nepalese study by Devkota et al. [21] found provider's attitude towards pregnant women with disability to be negative with poor knowledge and skills about service provision. In a Canadian investigation, Aragon et al. [1] noted that six percent of their respondents did not think they could safely treat a patient with epilepsy, because they lacked knowledge of people living with the disability. Along the same vein, Al-Adawi et al. [22] stated that the majority of their study participants in Oman thought that people with epilepsy have more predispositions towards dysfunctional personality and behavioural characteristics than do "normal" people. They suggested that a developing country like Oman must inculcate in their physicians more realistic attitudes towards individuals with epilepsy.

Our extensive search of the literature indicates that this is the first time in Nigeria the IDP Scale has been used to measure the attitudes of practicing healthcare providers towards PWDs. Healthcare providers are likely to be among the first individuals with whom a newly disabled person has contact, so their dispositions towards PWDs can have significant implications for implementing treatment, rehabilitation, and reintegration into the community. Yet, as has been shown in our review of previous studies, the literature is generally inconclusive about the attitudes of these professionals.

Our study findings indicate that healthcare workers who provide direct patient care are more comfortable when interacting with their patients with disabilities as compared to workers providing indirect care. Direct/indirect care provider status was not associated with the experiential variables level of prior contact with PWDs and knowledge of legislation regarding PWDs in this sample, but level of training specific to PWDs and confidence in treating PWDs were. Hence, it may be that a larger amount of specialised training leads to greater confidence in treating PWDs.

We found that older (age 44-60 years) healthcare workers express more feelings of vulnerability about becoming disabled. Age was not associated with the experiential variables with the exception of level of prior contact, for which there was no uniform trend. Hence, it

may be that we are simply capturing the recognition that, as one ages, the likelihood of experiencing a significant disabling condition is increasing, resulting in one's feelings of vulnerability.

The negative association that we observed between each of the three factor scores, discomfort, information and vulnerability, with level of confidence in treating PWDs provides support for the multi-dimensionality of the IDP Scale. Forlin, Fogarty and Carroll [23] preferred to label the factor Information as Uncertainty. Our findings indicate that less training specific to PWDs and less knowledge of legislation and policies result in more uncertainty in dealing with patients with disabilities.

A major take-away from this study is the need for healthcare providers to be adequately trained in disability-related topics while in residency or medical, nursing, or allied health professional training. Oredugba and Sanu [11], in their survey of dentists in Nigeria, alluded to this salient point when they commented that improved training would help the dentists better manage patient behaviour and utilise time effectively. Given the pervasive nature of disabilities in the Nigerian society today, proactive measures should be embarked upon so healthcare practitioners are sufficiently prepared to deal with existing and emerging disabling conditions [16]. We believe healthcare providers' attitudes can influence their behaviour towards their patients. Therefore, it is critical periodically to examine their attitudes towards their patients with disabilities who come to the hospital for treatment and care.

Recommendations

From the insights gained in this study, we recommend a number of measures to develop and sustain practitioners' attitudes towards PWDs and their families. First, there should be regular in-service training sessions where healthcare providers participate in structured role-plays to experience the use of the wheelchair around the premises, wearing ear plugs and using a blindfold with a human guide to simulate walking difficulty, deafness and blindness, respectively. Second, hospital management and staff could collaborate with the Joint National Association of Persons with Disabilities, an umbrella organisation of PWDs in Nigeria, to recruit competent guest speakers with disabilities and their families to share their experiences during in-service training sessions. Third, hospital management could organise healthcare providers' visits to special education schools and rehabilitation centres for PWDs to gain authentic insights into issues that impact the special populations.

Surveys at participating institutions before and after such educational interventions (including a scale such as the IDP) could be conducted to assess changes in attitudes towards persons with disability. Further and ongoing research on the attitudes, knowledge and practices of the providers would also help to determine, over a sustained period, if health-related government policies are being implemented to promote inclusive, quality healthcare for all PWDs.

Limitations of the Study

Because data for this project were gathered from one hospital, the nature of the sample limits the generalisability of the results. Therefore, we recommend expanded investigations to include selected hospitals in the six geopolitical regions of the country, including the Federal Capital Territory, Abuja. This would enable the researchers to capture responses from healthcare providers with a wider range of exposure to, and experience with, individuals with disabilities. This could result in a sample for which the total IDP Scale would prove to be a reliable indicator, as was shown for healthcare providers in other countries [24].

CONCLUSION

One notable aspect of our study is that three-quarters of participants were direct care providers, which is suggestive of the willingness of workers at UCH to implement specialized services. Significantly, over half of respondents indicated they had either daily or weekly interactions with patients with disabilities. However, only 11% reported having acquired at least 40 hours of disability-related training, and only 31% stated having either a high or very high level of confidence in treating PWDs. As members of the caring profession, direct- and indirect- healthcare providers have critical roles to play in the provision of quality health services. Therefore, it will behoove providers to be cognizant of the needs, wants and choices of PWDs. Furthermore, these healthcare providers must engage in frequent contact with PWDs in order to develop providers' confidence and foster organisational and individual capacities that will empower PWDs to live fully inclusive lives in their communities.

ABSTRACT

In this chapter we explore the interest of graduating medical students in the Usmanu Danfodiyo University (UDU), Sokoto, Nigeria, on taking up medical jobs in the Nigeria defence sector. Methods: This study was a cross-sectional questionnaire survey of 63 graduating medical students of UDU, Sokoto, Nigeria. Collected data was analysed using the SPSS version 16 software. Results: The mean ($\pm$ SD) age of the 63 respondents was 24.87 ($\pm$ 2.17) years, and the majority (73.0%) of them were males. Only 26 (41.3%) out of the 63 respondents showed interest in taking up a medical job position in the Nigeria defence sector, and the majority (22/26, 84.6%) of them were men. The majority (57.7%) of those respondents who desired working in this sector would like to work with the Nigeria Armed Forces (NAF), and their most desired arm of the NAF was the Nigeria Navy. Personal interest (65.4%), prestige (57.7%), and job security/advancement prospects (38.5%) were the top three motivating factors among those respondents that desired a medical job in the Nigeria defence sector. Conclusions: This study shows that only the minority of the surveyed graduating medics would like to take up a medical job

* Corresponding Author's Email: kehindekanmodi@gmail.com.

position in the Nigeria defence sector. Personal interest, prestige, and job security/advancement prospects were the predominant motivating factors among those that desired medical job positions in the Nigeria defence sector.

INTRODUCTION

There are diverse career paths to choose from after bagging a degree in human medicine. The work of a medical doctor goes beyond clinical and as a matter of fact, a medical doctor can also work as an administrator, a policy maker, an educator, or a scientist. For instance, if we focus on the Nigeria defence sector, we will observe that the services of medical doctors are seriously needed in the Nigerian defence sector. Some of the roles played by medical doctors in the establishments under the Nigeria defence sector includes provision of medical care to defence personnel and their family, provision of medical care to civilians at warring places and other conflict zones home and abroad, planning and execution of emergency medical care and services to victims of natural disasters, amidst other duties.

Globally, career choice of medical students in the defence sector had been sparsely reported. However, from the few studies available, it was found that career in the defence sector was very appealing to medical students in Pakistan and the United States of America [1, 2], and many factors had been documented to influence the career choice of these students in the defence sector. Some of these factors include national patriotism, high income, and attractiveness of the uniform [1, 2]. However, to the best of the authors' knowledge, no literature had particularly explored Nigerian medical students' choice of career with the Nigeria defence sector. Hence, authors aim to conduct this study to determine the level of interest of the graduating medics of the Usmanu Danfodiyo University (UDU), Sokoto, Nigeria, in pursuing a medical career in the Nigeria defence sector, and to also explore the factors that influence their career choice in this sector.

OUR STUDY

This research was a cross-sectional study conducted among the final year medical students of the UDU, under the ethical guidelines of the Helsinki Declaration. This institution is a public university situated within the metropolitan city of Sokoto, Nigeria. The instrument adopted for the study was a well-structured 27-item questionnaire developed through review of literatures [1, 3]. The questionnaire obtained information on the bio-data, interest of participants in taking up medical jobs in the defence sector, and the factors that influenced their choice of career in these job positions.

The study population comprises 98 graduating medical students. These students were approached at their classroom and dormitories. The aims and objectives of the study were clearly explained to them before obtaining verbal informed consents for participation. However, only 63 students volunteered to participate in this study. For the sake of confidentiality, an anonymous questionnaire was used for data collection. Data collection was done in November, 2017. Collected data was entered into the SPSS version 16 software for analysis. Frequency distributions of all variables were determined, and comparisons between

qualitative variables was done using Chi-square with the level of significance set to a p -value <0.05 .

Table 1. Demographic profile of respondents

Attributes (n=63)	Frequency (%)
Mean age in years ($\pm$ SD)	24.87 ($\pm$ 2.17)
Gender	
Male	46 (73.0)
Female	17 (27.0)

n=Total number of respondents.

Table 2. Comparison between gender of respondents and their interest of taking up a medical job in the Nigeria defence sector

		Gender		Total (N=63)	X^2
		Male (N=46)	Female (N=17)		
Can you take up a medical job in the Nigeria defence sector?	Yes	22 (47.8)	4 (23.5)	26 (41.3)	0.173, df=2
	No	16 (34.8)	10 (58.8)	26 (41.3)	
	Yet to decide	8 (17.4)	3 (17.6)	11 (17.5)	
	Total	46 (100.0)	17 (100.0)	63 (100.0)	

FINDINGS

The mean ($\pm$ SD) age of the respondents was 24.87 ($\pm$ 2.17) years. Gender distribution of the respondents was skewed with the majority (73.0%) of them being males (see Table 1). Only 26 (41.3%) out of the 63 respondents showed interest in taking up a medical job in the Nigeria defence sector, of which the majority (84.6%) of them (i.e., those who desired a career in the Nigeria defence sector) were men (see Table 2).

The majority (57.7%) of those respondents who desired working in the Nigeria defence sector would like to work in the Nigeria Armed Forces (NAF), and the most desired arm of the NAF was the Nigeria Navy (see Figure 1). Personal interest (65.4%), prestige (57.7%), and job security/advancement prospects (38.5%) were the top three motivating factors among those respondents that desired a medical job in the Nigeria defence sector (see Table 3).

Keywords: A=Nigeria Army; B=Nigeria Navy; C=Nigeria Prisons Service; D=Nigeria Air Force; E=Nigeria Police Force; F=Nigeria Security and Civil Defence Corps; G=Nigeria Customs Service; H=National Drug Law Enforcement Agency.

Figure 1. Places where those respondents who showed interest in working with the Nigeria defence forces desired (N=26).

Table 3. Factors influencing the career choice of those respondents that showed interest in taking up a medical job position in the Nigeria defence sector

Influencing factors	Gender*		Total (N=26)
	Male (N=22)	Female (N=4)	
Personal interest	16 (72.7)	1 (25.0)	17 (65.4)
Job security/advancement prospects	8 (36.3)	2 (50.0)	10 (38.5)
Lifestyle and the job description	9 (40.9)	0 (0.0)	9 (34.6)
Prestige	13 (59.1)	2 (50.0)	15 (57.7)
Flexibility of the profession	3 (13.6)	0 (0.0)	3 (11.5)
High wages	6 (27.3)	1 (25.5)	7 (26.9)
Easily compatible with having a family	5 (22.7)	1 (25.5)	6 (23.1)
Influence from a mentor	7 (31.8)	1 (25.5)	8 (30.8)
Enough time for leisure activity	3 (13.6)	0 (0.0)	3 (11.5)
Influence from a family or relative	3 (13.6)	1 (25.5)	4 (15.4)
Gender distribution in the job	6 (27.3)	1 (25.5)	7 (26.9)

N=Total number of respondents in each category.

DISCUSSION

Doctors-in-training in foreign countries like Pakistan and United States of America had been reported to show keen interest in taking up medical job positions with their homeland defence forces, after graduation from medical school [1, 2]; national patriotism, high income, and attraction for uniform, were the predominant motivating factors that were found to have influenced their choice of career with the defence forces of their country [1, 2]. Interestingly, to the best of the authors' knowledge, no similar study is available from a similar study population in Nigeria. The rationale for conducting this present study was to provide the first literature that explores Nigerian medical students' choice of medical career with the Nigerian defence forces.

In this study, it was observed that less than half of the respondents would like to take up a medical job position in the Nigerian defence sector (see Table 1). Most of those respondents that showed positive interest in working in the Nigerian defence sector preferred to work within the arms of the NAF (i.e., the Nigeria Army, Nigeria Navy, and Nigeria Air Force); this may be because the NAF is the most prestigious and powerful arm of the defence sector of Nigeria.

Interestingly, none of the female respondents in this present study would like to take up a medical career with the Nigerian Army, Nigerian Customs Service, and the National Drug Law Enforcement Agency. Unfortunately, the precise reasons why the female folks showed no interest in this study were not given in the scope of this study. However, this finding has generated research questions that need to be answered through further studies.

It is also noteworthy that the factors that informed the respondents' choice of career with the Nigeria defence forces are diverse and numerous. The top three influencing factors, among all, were personal interest, prestige, and job security/advancement prospects; interestingly, these top three factors were put into consideration by both genders. However, we observed that there were some other motivating factors that were not put into consideration by both genders. For instance, factors like job flexibility, lifestyle and job description, and enough time for leisure activities were not considered by any of the female

respondents; this finding is dissimilar with other existing studies on career choice among Nigerian students in clinical professions [3, 4], as the females in those studies considered these aforementioned factors.

Our findings have its implications. First of all, the majority of the surveyed medical students had no interest in working with the Nigeria defence forces; this may pose a problem to the holistic healthcare of the Nigerian security personnel if similar disinterest is recorded among medical students in other Nigerian medical schools. There also exists skewed distribution in the choices of the medical students, as many of them preferred to work in the Nigeria Armed Forces, while a scanty few would like to work in the paramilitary and police forces. This shows that some security agencies/forces may find it very difficult to recruit medical personnel into their setting as such agencies are not appealing to medical students, as demonstrated in this study.

Lastly, this study has its limitations. Firstly, this study did not enquire into reasons why the respondents showed no interest in medical careers in the Nigeria defence sector. Secondly, this study was a single centre study and it did not survey other graduating medics in other Nigerian medical schools; hence the need for multi-centre studies that will capture a larger population.

CONCLUSION

This study shows that many medical students would not want to take up a medical job positions in the Nigerian defence sector. However, the majority of those that would like to work in this sector preferred the NAF. Motivating factors like personal interest, prestige, and job security/advancement prospects were the most predominant factors that were found to influence medical students' decision in taking up a medical job positions in the Nigeria defence sector.

ACKNOWLEDGMENTS

This study is self-funded. Authors have no competing interest to declare. Also, this chapter was a revised version of an earlier publication of the authors [5].

ABSTRACT

Not all medical students want to further their education after bagging a medical degree. Even among those who want to further, not all of them want to pursue postgraduate disciplines in clinical medicine. This study aims to explore the postgraduate disciplines desired by the graduating medical students of the Usmanu Danfodiyo University (UDU), Sokoto, Nigeria, and also explore the factors that influenced their choice of a postgraduate study program. Methods: This study surveyed a cross section of 63 graduating medical students of the UDU using a well-structured anonymous questionnaire. Data obtained was analyzed using the SPSS version 16 software. Results: The mean age ($\pm$ SD) of the 63 respondents was 24.87 ($\pm$ 2.17) years, with the majority (73.0%) of them being males. Only 44 (69.8%), out of a total of 63, respondents desired to go for postgraduate studies after finishing medical school, of which the majority (89.2%) of them desired to pursue a medical residency program. Also, not up to half (39.5%) of those respondents who desired postgraduate study intended to have it done in an institution within Africa. The disciplines chosen by those respondents who desired postgraduate studies were diverse, however the majority (70.5%) of them prefer postgraduate programs in clinical sciences. Personal interest (75.0%) and research opportunities were the top two factors influencing the respondents' choice of a postgraduate study program. Conclusions: Not all medical students desired to further

* Corresponding Author's Email: kehindekanmodi@gmail.com.

their education after medical school. Also, the choices of postgraduate study programs among the surveyed students were diverse.

INTRODUCTION

After the completion of a medical degree program, a fresh medical doctor is born. As a fresh medical graduate, the next question to be asked is “What is the next task to embark upon?” Interestingly, different studies had shown that medical students have diverse preference for what to do after graduation [1-4]. Those studies showed that: some medical students prefer to go into general medical practice; some prefer to pursue further educational qualifications; while some prefer to pursue other career paths that may or may not be related to medicine, after graduation [1-4].

In actual fact, there are many postgraduate disciplines that could be explored by a medical doctor, if considering further studies. As a matter of fact, specialization in disciplines within the borders of clinical sciences is just an option, amongst a gamut of options. Some of the other disciplines that could be explored include some, if not all, disciplines in social sciences, humanities, law, basic medical sciences, and public health, among others.

However, many factors had been found to influence medical students’ choice of a postgraduate study program, some of which includes personal interest, ease of admission into the program, and prestige [1-4]. Also, many studies had elaborately explored medical students’ interest in residency training in the clinical specialties; however only scanty studies had been done on medical students’ interests in disciplines outside medical sciences [1-5].

This study aims to explore the interest of graduating medical students of the Usmanu Danfodiyo University (UDU), Sokoto, Nigeria, on various postgraduate study programs, and also explore the factors that influence their choice of the proposed area of postgraduate study.

OUR STUDY

This was a cross-sectional study undertaken among graduating medical students of the Usmanu Danfodiyo University (UDU). This institution is a public university situated within the metropolitan city of Sokoto, Sokoto State, Nigeria. This institution is also the home to the only medical school within Sokoto State. A total of 98 medical students were in the graduating class during the period this study was conducted.

Study tool was a well-structured 34-item anonymous questionnaire designed by the authors through the review of literatures [1-4]. Questionnaire obtained information on the: bio-data; interest of the participants in pursuing postgraduate studies after graduation; the postgraduate disciplines they would like to pursue; the continent where they would like to have the study program done; and the factors that influenced their choice of a postgraduate study program.

The participants were approached at their classroom and dormitories. The aims and objectives of the study were clearly explained to them before obtaining verbal informed consents. Only 63 students volunteered to participate in this study. Data collection was done in November, 2017.

A total of 63 questionnaires were analyzed for this study; no questionnaire was discarded because all were properly filled. Collected data was entered into the SPSS version 16 software for analysis. Frequency distributions of all variables were determined, and comparisons between qualitative variables was done using Chi-square with the level of significance set to a p-value <0.05.

FINDINGS

The mean age ($\pm$ SD) of the 63 respondents was 24.87 ($\pm$ 2.17) years and majority (73.0%) of them were males (see Table 1).

Only 44 (69.8%), out of a total of 63, respondents desired to go for postgraduate studies after finishing their undergraduate medical program (see Table 2), of which the majority (89.2%) of them desired to pursue a residency program (see Table 3). In addition, a higher proportion (80.4%) of the men, when compared to the women (41.2%) intended to further; this comparison was found to be statistically significant ($p = 0.005$, $df = 2$).

Table 1. Demographic profile of respondents

Attributes (n = 63)	Frequency (%)
Mean age in years ($\pm$ SD)	24.87 ($\pm$ 2.17)
Gender	
Male	46 (73.0)
Female	17 (27.0)

n = Total number of respondents.

Table 2. Comparison between gender of respondents and intention for postgraduate studies

		Gender of respondents			p-value (X^2), df
Do you intend to		Male (N = 46)	Female (N = 17)	Total (N = 63)	
further your	Yes	37 (80.4)	7 (41.2)	44 (69.8)	0.005, df = 2
education after	No	5 (10.9)	8 (47.0)	13 (20.6)	
having your medical	Yet to decide	4 (8.7)	2 (11.8)	6 (9.5)	
degree?	Total	46 (100.0)	17 (100.0)	63 (100.0)	

N = total number of respondents in each category, X^2 = Chi-square, df = degree of freedom.

Table 3. Postgraduate programs intended to be pursued by the respondents that showed interest in further studies

Postgraduate program	Male* (N = 37)	Female* (N = 7)	Total* (N = 44)
Masters	26 (70.3)	4 (57.1)	30 (68.2)
Doctorate	24 (64.9)	3 (42.9)	27 (61.4)
Residency program	33 (89.2)	5 (71.4)	38 (86.4)

*Only those that had the intention for postgraduate studies were analyzed here.

Not up to half (39.5%) of those respondents who desired postgraduate study intended to have it done in an institution within Africa (see Figure 1). Furthermore, disciplines in clinical sciences was the highest (70.5%) chosen discipline among those respondents who desired postgraduate studies (see Table 4).

Figure 1. Continental distribution of places where respondents desired to have their postgraduate education.

Table 4. Educational disciplines desired to be pursued by those respondents that desired postgraduate education

Discipline	Gender	
	Male (N = 37)	Female (N = 7)
Social sciences	2 (5.4)	0 (0.0)
Biological sciences	1 (2.7)	0 (0.0)
Public health	20 (54.0)	7 (100.0)
Basic medical sciences	10 (27.0)	4 (57.1)
Clinical sciences	26 (70.2)	5 (71.4)
Physical sciences	3 (8.1)	0 (0.0)
Humanities	2 (5.4)	0 (0.0)
Arts	1 (2.7)	0 (0.0)
Engineering	2 (5.4)	0 (0.0)
Law	3 (8.1)	0 (0.0)

Of all other influencing factors, personal interest was found to be the most popular (75.0%) influencing factor on the respondents’ choice of a postgraduate study program. However, factors such as gender distribution in a study program, and other people’s perception of the qualification obtained from the study program were the least popular (6.8%) influencing factors among them (see Table 5).

Table 5. Factors influencing respondents' choice of a postgraduate discipline

Influencing factors	Gender*	
	Male (N = 37)	Female (N = 7)
Personal interest in the study program	27 (73.0)	6 (85.7)
Job security/advancement prospects	14 (37.8)	1 (14.3)
Ease of entry into the study program	9 (24.3)	1 (14.3)
Lifestyle and the job description	16 (43.2)	2 (28.6)
Prestige	11 (29.7)	0 (0.0)
Opportunity to conduct research	16 (43.2)	3 (42.9)
Flexibility of the study program	8 (21.6)	3 (42.9)
Contact with patient and clinical samples	15 (40.5)	2 (28.6)
High wages	9 (24.3)	1 (14.3)
Easily compatible with having a family	9 (24.3)	2 (28.6)
Inclination of the study program before entering medical school	4 (10.8)	0 (0.0)
Influence from a mentor	9 (24.3)	2 (28.6)
Enough time for leisure activity	12 (32.4)	4 (57.1)
Influence from a family or relative	5 (13.5)	1 (14.3)
Other people's perception of the qualification obtained from the study program	3 (8.1)	0 (0.0)
Low risk of litigation	8 (21.6)	1 (14.3)
Gender distribution in the study program	3 (8.1)	0 (0.0)

N = Total number of respondents in each category, *only those that indicated interest in pursuing postgraduate studies were analyzed here.

DISCUSSION

Studies had shown that not all medical students wish to further their education after bagging a medical degree [4, 6]. Furthermore, among those medical students who intended to further their education, not all of them want to go for residency training [4]. In this present study, only 69.8% of the surveyed graduating medical students had the intent to further their studies, of which only 86.4% of them desired to go for residency training. This finding is lower than that reported in a previous Nigerian study, where 89.5% of the respondents in that study desired to go for residency training [7].

It is noteworthy that lack of intent to pursue a postgraduate study program was found to be more common among the female respondents when compared to their male counterparts. In fact, many female medical students do want to get married as soon as possible, after graduation, and start giving birth to children [6]. Hence, the challenge of combining family responsibilities with studying may be a major reason why many of the female respondents showed no interest in postgraduate studies [8].

Furthermore, not all of the respondents considered going for postgraduate study in disciplines within medical sciences, as some of them prefer pursuing postgraduate degree programs in arts, biological sciences, engineering, law, humanities, physical sciences, public health, and social sciences. This finding corroborates with that reported among medical students in Korea [4, 5].

It is interesting to note that less than four-tenth of the study respondents who desired to pursue postgraduate studies desired to have it done in Africa. This may suggest that postgraduate qualifications from institutions domiciled in Africa are less appealing to the majority of these medical students.

The factors that influence the respondents' choice of a postgraduate study program are diverse. Personal interest was found to be the most popular influencing factors among the respondents. Similar attribute had also been demonstrated among students in other clinical disciplines [9, 10]. Opportunity to conduct research, contact with patients and clinical samples, study program's flexibility, high wages, easy compatibility with having one's family, and ease of entry into a study program, were also factors that jointly influenced both the participating men and women.

We also observed that prestige, inclination of the study program before entering medical school, other peoples' perception of the qualification obtained from such study program, and gender distribution in such study program were the motivating factors that informed the women's choice of a postgraduate study program; however these factors did not inform the men's choice.

CONCLUSION

This study had shown that not all medical students desired to further their education after obtaining a medical degree. Among those that intended to further, not all of them want to go residency training, rather some wish to pursue degrees in fields outside medicine.

ACKNOWLEDGMENT

Chapter 373

BARRIERS TO UPTAKE OF LOW VISION AIDS AMONG VISUALLY IMPAIRED ELDERLY NIGERIAN PATIENTS

***Patrick Okonji*, OD, MPH, PhD
and Darlington Ogwezzy, OD, MBBS***

Research and Innovation Office, University of Lagos, Akoka-Yaba,
Lagos and Delta State School of Health Technology,
Ughelli, Delta State, Nigeria

ABSTRACT

While low vision aids enhance possibilities of reading, performing daily tasks and distant viewing for visually impaired individuals, there is paucity of research on their usage and adoption among Nigerians with low vision. Objective: This study attempts to bridge the knowledge gap about non-use of low vision aids among visually impaired older adults. Methods: Data concerning visually impaired older adults non-use of Low Vision Aids (LVAs) was collected and analysed through a cross-sectional survey in a Southwest city in Nigeria. Participants were 230 visually impaired non-users of LVAs aged 60 years and over. Results: Findings show that most non-users who were not aware of LVAs were less likely to be males, more likely to be aged over 71 years, and less likely to be middle and high educated compared to lower educated older adults. Participants aged 71 years and over were also less likely to consider future use of LVAs compared to other participants aged between 60 and 70 years. Visually impaired older adults with low levels of education were also significantly less likely to have intentions of using LVAs. Conclusion: The differences identified were mainly related to socio-demographic variables such as age, gender, household composition, and severity of vision impairment. This study highlights the importance of understanding how groups of visually impaired older adults will most likely benefit from interventions aimed at promoting uptake of LVAs and facilitating independent living among this population.

INTRODUCTION

Low vision refers to irreversible loss of vision which makes activities of daily living difficult for a person to perform [1]. It is defined as visual acuity ranging from light perception to $<6/18$ (0.3 logMAR), or a visual field smaller than 10 degrees from the point of fixation even after treatment and/or standard refractive correction [1]. However, low vision taken together with blindness represents all visual impairment [1, 2]. People with low vision are, however, capable of using their residual vision and if given appropriate low vision aids and training, they do not typically need to function with additional or complementary support. In principle, many patients with low vision are not technically considered blind, although they might be classified as such. With increasing global population, the prevalence of visual impairment is increasing [2].

However, the provision and uptake of low vision services and low vision aids (LVAs) continues to be relatively low particularly in the developing countries [3, 4]. In some developing countries, such as India, research focus is shifting towards identifying avenues for effective provision and uptake of low vision services [5, 6]. In this context, efforts are increasingly channelled towards having data on the knowledge and awareness of low vision services among patients and eye care practitioners, and to improve quality of low vision care in the developing world [5-9].

The aim of this study was to investigate barriers to the uptake of low vision aids among visually impaired older adults in Nigeria in order to create understanding of how they can be encouraged to embrace the use of LVAs. Our focus is on older adults because it is estimated that 80 per cent of all people who need low vision care in are aged over 60 years [10]. The research question explores the extent to which major barriers to accessing low vision aids hinder visually impaired older people in Nigeria from adopting LVAs. It also seeks to provide explanations on associated key factors for low uptake of low vision aids.

Low vision aids and products include a wide variety of devices designed to help those with vision disabilities live independently and make the best use of their residual vision. There are a variety of talking products that can help alleviate eye strain and improve daily living, including talking calculators, compasses, scales, cooking items, clocks, money identifiers, scales, medication reminders, talking watches, books and much more. These simple-to-use and sometimes, technology driven aids enable visually impaired individuals to take care of themselves and not have to rely on others for support. Low vision aids are frequently categorized as optical, non-optical, and electronic aids. Optical aids are useful for people with low vision as they have optical properties capable of promoting better distance and near visual performance through lenses, e.g., Telescopes (hand-held, monocular and/or binocular telescopes), High-plus spectacles (microscopes), Hand-held magnifiers, and Stand magnifiers. As optical aids require use of residual vision, they are usually more useful for individuals with low vision than for totally blind persons [11]. Non-optical aids do not use magnifying lenses to improve visual function, e.g.,; typoscope used as a guide to reading, writing, and signature in cases of large defects of visual field, polarizing lenses used to control the reflection of light such as visors, and side shields. Electronic aids include computer and high-tech aids such as video magnifier systems, closed-circuit televisions, Bluetooth connections to smart projectors, large-print computer programs such as Zoom Text,

screen readers such as Virtual Vision, Jaws, and electronic-based aids for daily living, e.g., talking clocks/wristwatches are aids with computer sound systems.

While low vision aids are essential products for low vision rehabilitation, there is scarcity of data on their use and adoption among visually impaired persons in Nigeria, as well as many developing countries. Evidence suggests that some individuals with vision impairment are, however, unaware of the myriad of low vision devices that are available and applicable to them, and others may be aware but chose not to use them [11]. This is particularly a significant concern; considering that the prevalence of blindness in developing countries, is higher than developed countries. Based on figures from the Nigerian National Blindness and Visual impairment survey, it is estimated that over 2.3 million individuals suffer low vision in Nigeria [12, 13]. There is a huge challenge of providing low vision services and rehabilitation for such a large population and it is important to create understanding about handy devices that can ameliorate the day-to-day challenges of living with vision impairment. In addition, the dearth of facilities and/or skilled personnels for low vision rehabilitation in Nigeria underscores the importance of interventions focusing on restoring the blind individuals' functional capacity pending other treatment alternatives. There are evidences suggesting that effective use of low vision aids promotes successful adjustment to challenges of living with vision impairment [14, 15].

In a review of existing literature regarding barriers that hinder access to low-vision (LV) care from the perspective of individuals with vision impairment, a Canadian study showed that lack of understanding about low vision services, inadequate information and miscommunication by eye care professionals, low levels of awareness about low vision care, and the need to appear independent were major barriers to accessing low vision services [16]. Other factors identified by the study include negative societal views and stigma associated with use of low vision aids. However, the existence of low vision services is not synonymous to use and uptake of low vision aids. Detailed surveys in some rural communities in Nigeria have found very low uptake of public healthcare facilities despite being, in principle, within geographic proximity and free of charges [17]. Understanding access to low vision services could foster knowledge, awareness, professional recommendation and use of low vision aids.

A study conducted among ophthalmologists in Nigeria cited non-availability of low vision devices within the country, lack of public awareness of low vision care, lack of training in low vision care, and practitioners (ophthalmologists' and optometrists') preoccupation with general ophthalmic practice as the major barriers in clinical low vision provision [18]. Although the study focused on ophthalmologists in Nigeria, there has not been any study exploring perceptions of the end-users; i.e., the visually impaired patients, to understand the challenges of non-use from their perspective. This study therefore, attempts to bridge the knowledge gap about non-use of low vision aids from the views of intended end-users.

OUR STUDY

The study employed a cross-sectional survey method. This study adhered to the tenets of the Declaration of Helsinki and ethical approval was obtained from the Research and Ethics Committee of the School of health. Participants were aged 60 years and over. The eligibility criteria for the study included best corrected visual acuity of $<6/18$ in the better eye, 60 years

of age and over, and the ability to read and converse in English. Participants were recruited during their routine follow-up visits in 14 registered eye clinics in the metropolitan cities of Lagos state and Delta state in Nigeria. A total of 323 visually impaired older people were contacted from 14 private eye clinics in Delta-state and Lagos state, Nigeria. The private clinics were randomly selected from five local government areas in Delta state and nine local governments in Lagos state. The study typically gathered data from surveys of views or opinions of participants as well as past clinical records of routine eye examinations. It was conducted in accordance with institutional and national guidelines for conduct of research with human subjects. The investigation was carried out in accordance with the Declaration of Helsinki of 1975 (As revised in Tokyo in 2004). Informed consent was obtained from all participants as they were briefed about the study and their verbal consent obtained before participation. Consecutive consenting respondents visiting the registered private clinics in the two states were recruited for the study. A structured interview questionnaire to ascertain socio-demographic details of participants was read out to participants and their responses recorded. Participants' low-vision case files were accessed, with their consent, to obtain relevant data on vision impairment. Of the 323 participants contacted over a period of eight months during the sampling phase of the study, 281 participants (86.99%) indicated that they did not use LVAs and were recruited to participate in the survey. However, a total of 230 participants (81.85%) participants completed the survey. Measures including: Age, gender, and vision acuity were considered as independent variables in analyses concerning non-use of LVA (see Table 1). Vision Acuity (VA) was measured using computerized Snellen chart and corresponding LogMAR values of the Snellen ratio were recorded.

Table 1. Demographic profile of participants

	N	%
Gender		
Male	92	40.00
Female	138	60.00
Age		
60-65	55	23.91
66-70	52	22.61
71-75	60	26.09
76+	63	27.39
Education		
Low	143	62.17
Medium	64	27.83
High	23	10.00
Household composition		
Single	43	18.70
Living with others	187	81.30

In the survey, participants were asked about how much they relied on others to perform daily tasks (also referred hereafter as activities of daily living). Questionnaires were printed in large fonts for partially sighted participants and read aloud for participants with severe low vision and totally blind. Appropriate boxes corresponding to their responses were ticked on the questionnaires. Dependent variables were Lack of knowledge or awareness of LVAs, Asking others for help (relying on others to perform daily living tasks), and Intended future use of LVAs. The question about Lack of awareness and Intended future use of LVAs

allowed respondents to answer with yes or no. Yes was coded as 1 and no = 0. Sample questions on asking others for help included, 'I have difficulties telling the time on the clock, but I do not need a LVA because I rely on others to tell me what time of the day it is', 'I find it difficult to read, but I do not need a LVA because I rely on others to read out any printed document to me'. The question on asking others for help allowed respondents to answer on a 4-point scale: 1 (strongly agree), 2 (agree), 3 (disagree), and 4 (strongly disagree). All scores were recoded and lower scores corresponded to higher levels of reliance on others to perform tasks of daily living and therefore, not needing a LVA. Dichotomous key variables of reasons for non-use of LVAs were included. We conducted a Hierarchical logistic regression analyses using IBM SPSS statistics version 18. We initially used two-step models to investigate whether the effects of gender, education, and household composition changed with vision acuity, but as these variables did not affect the original model, we report only the final regression analysis.

FINDINGS

Among the participants, 61 percent indicated not being aware of LVAs (Mean score (M) = 0.21, and Standard Deviation (SD) = 0.41). Table 2 shows that, the non-users who were not aware of LVAs were less likely to be males, more likely to be aged over 71 years than aged between 60 and 70 years, and less likely to be middle and high educated compared to lower educated older adults. However, among this group, participants who live with others were more likely to have knowledge of LVAs than those living alone and respondents with lower vision acuity seemed to have higher knowledge and awareness of LVAs.

Approximately 58 percent of participants reported having asked someone else for help on a task requiring vision. Mean scores (M) and Standard Deviation (SD) for the variables are: M = 1.62, SD = 0.41). Men were less likely to request for help. Similarly, participants aged

between 66 and 70 were more likely to request for such help compared to other age groups of visually impaired older adults. Participants living with others were significantly more likely to ask someone for help while participants with lower vision acuity were less likely to request for help. Only 23 percent of the participants indicated intentions to use LVAs in the future ($M = 0.78$, $SD = 0.42$). Participants aged 71 years and over were less likely to consider future use of LVAs compared to other participants aged between 60 and 70 years. Visually impaired older adults with low levels of education were also significantly less likely to have intentions of using LVAs. A lower visual acuity also suggested a higher likelihood of intention to use LVA in the future.

Explanations for non-use were also investigated. Table 3 shows tests of significance in differences for most important reasons for not adopting use of LVAs. The results showed that among visually impaired older adult men and women, a majority of men are more likely to not see the need for use of a LVA. Older adults aged 60-70 years were significantly more likely to report stigma as a discouraging factor for use of LVAs while older adults aged 76 years and over were significantly more likely to mention being too old to use LVAs. However, while participants with more education were significantly less likely to mention that there was ‘no need’ for LVAs, those who lived with others were significantly more likely to mention that there was no need for LVAs.

DISCUSSION

This study set-out to investigate non-use of LVAs among visually impaired older people aged 60 years and over and important reasons for non-use. A majority of our participants reported not being aware of LVAs. This finding echoes the report from previous (and similar) studies that lack of public awareness about low vision care is a significant impediment to uptake of low vision aids and related services [4, 18]. Findings suggest that, the non-users

who were not aware of LVAs were less likely to be males, more likely to be aged over 71 years, and less likely to be middle and high educated compared to lower educated older adults. While findings echo a previous report that highly educated individuals are more aware of the existence of LVAs and much older participants - less technologically inclined [12], there is paucity of evidence that knowledge and awareness of LVAs is gender based. The use of LVAs might not be a male-dominated activity but stereotypically, males have been considered good with use of gadgets and historically reported as being more ICT-inclined than females [19] because women underestimate themselves in this regard [20].

Our findings also showed that a lower vision acuity was significantly related to higher knowledge or awareness of LVAs. Arguably, more severely low vision patients could be keener and more enthusiastic about exploring solutions that would remedy their sight loss in order to avoid total blindness [21]. Conversely, patients with mild and moderate vision impairment are usually hopeful that their sight loss is reversible, and as such, more likely to be complacent with seeking low vision aid [4]. This is further underscored in findings from this study showing that a lower visual acuity indicated a higher likelihood of intention to use LVA in the future.

Some participants reported having asked someone else for help on a task requiring vision. Findings from this study showed that when considering gender, men were less likely to request for help. This finding is consistent with previous studies showing that men are less likely to admit weakness and seek medical attention [22]. It is therefore not surprising that in the investigated explanations for non-use conducted within this study, men were more likely than women to not see the need for use of a LVA.

Our participants who lived with others were more likely to report that there was no need for LVAs. This is not surprising as living with others could enhance access to alternative assistance to performing daily activities and living alone could possibly steer a compelling need for independent living aids. Similarly, participants aged between 66 and 70 years were more likely to request for help compared with other age groups of visually impaired older adults. It is possible that older participants with vision impairment have learnt ways to adapt to sight loss. As suggested by some authors, people who have lived with severely low vision for long periods are more likely to have learnt to lead independent lives than others in their early stages of mild or moderate vision impairment [23]. Similarly, participants aged 71 years and over were less likely to consider future use of LVAs compared to other participants aged between 60 and 70 years. This could perhaps be so because they considered themselves too old to use LVAs and seem not to see any point in adopting use of LVAs at old ages when they have already learnt to make adjustments to cope with sight loss. Findings also showed that visually impaired older adults with low levels of education were also less likely to have intentions of using LVAs. This is not surprising given that those with higher levels of education might still see the need for use of LVAs for reading and other activities related to accessing printed materials.

From our findings, older adults aged 60-70 years were more likely to report stigma as a discouraging factor for use of LVAs while older adults aged 76 years and over did not see this as an issue. There are on-going debates that use of assistive technologies could be stigmatizing [24, 25]. In some societies, social stigma still surrounds blind people due to misconceptions about blindness [16, 26]. It is, however, yet to be reported that younger age groups are more cautious of the potential for stigmatising identities than older age groups. It could be argued from this aspect of the study finding that the younger age groups might be a

potentially challenging group for interventions to promote adoption of LVAs among people with vision impairment. This finding adds novel understandings to the issue of social stigma and other factors impairing adoption of LVAs among visually impaired groups.

This study has some limitations. Due to the low sample size, our sample may not be fully representative of older adults' non-LVA users. Although the explored explanatory variables for non-use of LVAs among participants are moderate and consistent with previous studies of older adults' adoption of assistive technologies, it is not necessarily exhaustive. Future research should make investigate additional explanatory factors that can provide more robust explanations for visually impaired older adults' non-use of LVAs. This study investigated LVA non-use among older people in Nigeria – an emerging economy country with relatively lower availability of LVAs when compared to many first world countries. It would be insightful to replicate this study in other developing countries with similar levels of LVA and low vision services availability.

CONCLUSION

This study looked at visually impaired older adults' non-use of LVAs and other socio-psychological variables that may account for poor uptake of LVAs in Nigeria. The results showed that visually impaired older adults are likely to have different reasons for (dis)engagement with LVAs. The differences identified were mainly related to socio-demographic variables such as age, gender, household composition, and severity of vision impairment. This study highlights the importance of understanding how groups of visually impaired older adults will most likely benefit from interventions aimed at promoting uptake of LVAs and facilitating independent living among this population. However, more research is needed to understand attitudes of this population towards LVAs as vision impairment is not a homogenous concept and refers to a broad spectrum of needs with different levels of complexity

CONFLICT OF INTEREST

The authors declare that there is no conflict of interest regarding the publication of this paper.

ABSTRACT

Secondhand shisha smoke exposure is a cause of tobacco-induced diseases. There is a need to for the enforcement of law against shisha smoking in public places. This study aims to explore the attitudes of active shisha smokers towards the ban of shisha smoking in public places in Nigeria. Methods: A snowballed sample of 45 active shisha smokers

* Corresponding Author's Email: kanmodikehinde@yahoo.com.

in Birnin Kebbi was interviewed using a self-administered questionnaire. Data collected was analyzed using the SPSS version 20 software. Results: The mean ($\pm$ SD) age of the surveyed active shisha smokers was 25.8 ($\pm$ 5.5) years, and 32 were males. Less than a third (11/45) had ever heard of the Nigeria tobacco ban law, while only a little above half were in support of tobacco ban. Conclusion: The Nigeria tobacco ban law is not popular. Despite the fact that the surveyed subjects were active shisha smokers, a majority still supported the ban of shisha smoking in public places.

INTRODUCTION

Secondhand tobacco smoke exposure is one of the major causes of tobacco-induced diseases [1-3]. Unfortunately, a lot of Nigerians are exposed to these smokes [4, 5]. As a matter of fact, about 14.5-55.8% of the youth living in major Nigerian cities had been exposed to this dangerous smoke in public places [4, 6, 7], making exposure to tobacco smoke an issue of public health concern in Nigeria.

In the month of May, 2015, the Federal Government of Nigeria passed the tobacco control bill into law, prohibiting smoking of tobacco in public places (such as gardens, amusement parks, schools, restaurants, healthcare centers, stadia, public transportation parks and plazas) [4]. However, the enforcement of the ban was focused on cigarettes and not shisha, as more and more public shisha smoking places are being erected in the major cities in Nigeria [6-9]. As a matter of fact, shisha is generally considered by the public to be a fairly harmless product, while in the actual sense shisha use is very harmful due to its tobacco content [10-14]. Unfortunately, more and more people in Nigeria are now using shisha, day by day [8, 9]. With the weak enforcement of tobacco ban law in Nigeria, which does not restrict the public use of shisha, many more people will continue to be active, and even passive, shisha smokers [8, 9].

Research in Nigeria had reported negative attitudes among cigarette smokers (a sub-population of smoked tobacco users) toward the Nigeria tobacco ban law [15]. However, to the best of our knowledge, no published study had ever been conducted among shisha smokers in Nigeria concerning their attitudes towards this ban law. Therefore, this study aims to explore the attitudes of a sample of active shisha smokers in Birnin Kebbi metropolis, Nigeria, on the tobacco ban law in Nigeria. The significance of this study is that the outcome of this study will add new information to the body of existing knowledge on smokers' attitudes toward the tobacco ban law.

OUR SURVEY

This was a survey of 45 young active shisha smokers in Birnin Kebbi City, Kebbi State, Nigeria, which was conducted under compliance with the 1964 Helsinki Declaration on health research involving human subjects. This study forms a part of the Campaign for Head and Neck Cancer Education (CHANCE) Program organized under the aegis of the Cephas Health Research Initiative Inc, Ibadan, Nigeria [7-9, 16-17].

The sampling method and the data collection procedure used in this present study had been elaborately discussed in another article [9]. Study tool was a structured anonymous

questionnaire developed from a similar study [7]. The questionnaire obtained information about the socio-demographic characteristics of the subjects as well as their attitudes toward tobacco ban law. Data was collected from 45 active shisha smokers. Collected data was analyzed using the SPSS version 20 software.

FINDINGS

The mean ($\pm$ SD) age of the surveyed active shisha smokers was 25.8 ($\pm$ 5.5) years. The majority (32/45) were males, 16 had secondary school education, 27 had tertiary school education, 33 were Muslims, and 28 were from the Hausa ethnic group.

Only 11 respondents knew that there is a ban on tobacco smoking in public places in Nigeria. However, only 27 agreed that shisha sales to adolescents should be banned, 23 agreed that the advertisement of shisha and shisha products should be banned, 30 agreed that shisha smoking should be banned in restaurants, 25 agreed that shisha smoking should be banned in bars/discos/pubs, and 20 agreed that shisha smoking in all enclosed public places should be banned.

DISCUSSION

The issue of tobacco smoking in public places continues to be an issue of public health concern in Nigeria. Due to the weak enforcement of the tobacco ban law in Nigeria, many cigarette smokers in Nigeria still engage in public smoking [4-6]. Due to this, more and more people have become passive tobacco smokers due to their frequent exposures to second-hand tobacco smokes [4-6]. Due to the issue of weak law enforcement of the tobacco ban law in Nigeria, more and more shisha smoking places (such as discos, restaurants, hubs, etc.) had been erected in some Nigerian major cities [8, 9]. Hence, this issue needs to be considered as a public health emergency.

Furthermore, the peculiarities of shisha smoking make public shisha smoking more dangerous than cigarette smoking. First, shisha is naively perceived by the many lay people, and even among its active smokers, to be a harmless product [10-14]. Second, shisha smoking is widely considered as a socially acceptable behavior, unlike cigarette smoking [18-21]. Third, many shisha smokers smoke shisha in enclosed public areas (such as restaurants, discos, hubs, etc.) unlike cigarette smokers, where a huge number of cigarette smokers smoke in the open air (e.g., along the street) [9]. Fourth, shisha smokers often smoke shisha for a long duration, especially at social gatherings [22]; hence they have the high possibility of inhaling more tobacco smokes in one sitting.

In this study, we surveyed a snowballed sample of shisha smokers on their attitudes towards banning shisha smoking in public places and interesting findings were recorded from our data analyses. We found that the majority of the surveyed shisha smokers were not aware about the tobacco ban law in Nigeria. This current finding is similar to that reported in a Nigerian study conducted among cigarette smokers by Olowookere et al. [15], where a very low awareness rate of tobacco ban was reported. This suggests the need to educate smokers, and as well the entire public on the Nigeria tobacco ban law.

However, the majority (although, averagely above half) of the shisha smokers surveyed in this study supported that shisha smoking in public places should be banned. This finding is dissimilar to that reported among a surveyed sub-population of cigarette smokers in Osun State, Southwest Nigeria, where only the minority of them were in support of tobacco ban. Nevertheless, the findings made from our study and that of Olowookere et al. [15] reveals that not all smokers (be it shisha or cigarette) are against the implementation of the tobacco ban law in Nigeria. In conclusion, the Nigeria tobacco ban law is not popular and it is also weakly enforced in Nigeria [15]. Despite the fact that the surveyed subjects were active shisha smokers, majority of them still supported the ban of shisha smoking in public places.

ABSTRACT

Pain management is a very important aspect in the holistic care of patients. The clinical practitioner's knowledge of the pharmacology of pain killers goes a long way in the effective control of pain. Objectives: To assess the level of knowledge of clinical practitioners in Sokoto metropolis, Nigeria, on the pharmacology of non-opioid analgesics (NOAs). Methods: This study utilized the primary data obtained from a cross-section of 175 clinical practitioners working in five randomly selected hospitals situated within the metropolitan city of Sokoto, Nigeria. The study tool was a 17-item questionnaire. Data analysis was done using the SPSS version 16 Software. Results: Less

than four-tenth (36.5%) of the subjects were within the age bracket of 26 to 30 years. 62.3% were males, 45% were nursing officers, and 36% had less than six years of experience in clinical practice. None of the surveyed pharmacists strongly disagreed that they were knowledgeable about the metabolism of NOAs, unlike the subjects in other occupational categories ($p < 0.0001$, $df = 12$). All of the surveyed dentists knew of the World Health Organization (WHO) analgesic ladder, unlike the other subjects in the other occupational categories ($p = 0.001$, $df = 12$). A range of 30 to 40% of the nurses, medical doctors, and pharmacists surveyed in this study considered tramadol to be a NOA. Paracetamol, ibuprofen, and diclofenac were the top three commonly prescribed NOAs among the subjects. The most common side effects of NOAs known to the subjects were nausea, vomiting, and peptic ulcer disease (PUD). Conclusion: Many of the surveyed subjects had inadequate knowledge of NOAs. This study population will highly benefit from educational programs that are focused on the clinical use of NOAs.

INTRODUCTION

The knowledge of a clinical practitioner on the pharmacology of pain killers is very important in patient management. In fact, it is virtually impossible for a practicing clinical practitioner not to prescribe, administer or dispense analgesic medications in his/her entire lifetime of clinical practice; hence this reflects the need for a clinical practitioner to have a very sound knowledge on pain management.

Pain can be managed pharmacologically and/or non-pharmacologically [1-5]. The pharmacological management of pain involves the use of drugs [1, 2], while the non-pharmacological management involves the use of other means, such as acupuncture, acupressure, behavioral therapy, and physical therapy [3-5].

One of the main groups of drugs used in the pharmacological management of pain is known as analgesics [1, 2]. The analgesics are broadly classified into the opioid analgesics (OAs) and the non-opioid analgesics (NOAs). The OAs are known to be more potent in pain control than the NOAs [6]; however one of the major problems associated with the use of OAs is the risk of dependence or tolerance [7].

It is an unbeatable fact that the NOAs still remain as the most commonly prescribed analgesics globally. After thorough literature search, authors noticed that the majority of the available literatures assessing clinicians' knowledge of analgesics were focused on OAs while only few literatures assessed clinicians' knowledge of NOAs. This study aims to assess the level of knowledge of doctors, nurses, and pharmacists in Sokoto metropolis, Nigeria, on the pharmacology of NOAs. Conducting this kind of study among this population group is of high significance as the outcome of the study will provide information on how knowledgeable they are on the pharmacology of NOAs.

OUR STUDY

This was a cross-sectional study conducted under the ethical guidelines of the Helsinki Declaration on health research involving human subjects. Approval to conduct this study was officially obtained from the Ethical Clearance Committee, Ministry of Health, Sokoto State,

Nigeria (Ref. No: SKHREC/068/017). All subject participation was absolutely voluntary, and all identities were kept strictly confidential.

The instrument used for data collection was an anonymous well-structured 17-item questionnaire. This questionnaire had three sections. The first section obtained information on the bio-data of the participants. The second section obtained information from the participants on their knowledge of the: pharmacology (route of administration, dosage, and, adverse effects) of NOAs; and management of complications associated with NOA overdose. The third section obtained information from the participants on the frequency at which they prescribe NOAs to patients.

This study was a survey of nurses, medical doctors, pharmacists, and dentists working in five hospitals situated within the metropolitan city of Sokoto, Nigeria. A total of 188 consenting participants were recruited for this study using simple random sampling technique. Each of the participants was issued a paper questionnaire to fill and return. Only 175 (93.1%) out of the 188 participants returned their questionnaires filled. None of the returned questionnaires was discarded, because all were properly filled.

Data analysis was done using the SPSS version 20 software. The frequency distributions of all variables were determined, and tests of associations between variables were done using the Chi-square test with a p -value of < 0.05 considered to be of statistical significance. The statistical results obtained were presented using tables.

FINDINGS

About four-tenth (36.5%) of the 175 subjects were within the age bracket of 26 to 30 years. 62.3% were males, 45% were nursing officers, and 36% of them had less than six years of experience in clinical practice (see Table 1). None of the surveyed pharmacists strongly disagreed that they were knowledgeable about the metabolism of NOAs, unlike the subjects in other occupational categories ($p < 0.0001$, $df = 12$). Furthermore, less than 40% of all the subjects in each occupational category strongly agreed that they knew the dosage of NOAs ($p = 0.066$, $df = 12$). It is also noteworthy that all of the surveyed dentists knew of the World Health Organization (WHO) analgesic ladder, unlike other subjects in the other occupational categories ($p = 0.001$, $df = 12$) (see Table 2). Interestingly, a range of 30 to 40% of the nurses, medical doctors, and pharmacists surveyed in this study considered tramadol to be a NOA (see Table 3).

Amidst other findings presented in Table 4, it is noteworthy that just only 9.0% and 7.1% of the surveyed nurses and pharmacists, respectively, did not prescribe NOAs to patients (see Table 4).

Paracetamol, ibuprofen, and diclofenac were the top three commonly prescribed NOAs among the subjects (see Table 5). The three most common side effects of NOAs known to the subjects were nausea, vomiting, and peptic ulcer disease (PUD) (see Table 6).

Lastly, the three most common route of administration of NOAs known by the subjects were intramuscular, intravenous, and the oral routes (see Table 7).

DISCUSSION

This study surveyed a sample of nurses, dentists, medical doctors, and pharmacists working in five major hospitals situated within the metropolitan city of Sokoto, Nigeria, on their knowledge of the pharmacology of NOAs. The significance of this study was that it provided information on subjects' level of knowledge on NOAs (the NOAs are the first line of drugs in pain management [8]).

Pain is a common symptom in many disease conditions. In patient management, pain control is a very important aspect that needs to be put into consideration. Pain management in a hospital setting involves a multidisciplinary approach. Starting from the doctor, after clinical diagnosis has been made, analgesics are prescribed to the patient in a prescription note. Thereafter, the drugs are dispensed by the pharmacist before being finally administered by the nurse.

Based on the above, a clinical practitioner needs to have a very sound knowledge of the pharmacology of NOAs. From the findings made in this study, it can be said that the knowledge of many of the subjects was inadequate. First of all, not all of them had sound knowledge of the metabolism and dosage of NOAs. This is noteworthy because these individuals are actively involved in patient management; hence their knowledge deficits in pain management may tell negatively on the proper management of their patient.

Secondly, some of the subjects did not know the class of analgesics where tramadol belongs to, as many of them considered tramadol to be a NOA. Tramadol is an OA which is known to cause dependence [9, 10]; it is also one of the abused drugs in the environment where this study was carried out [11]. Unfortunately, the wrong understanding of tramadol as a NOA among the subjects might have made some of them prescribed this drug irrationally to patients increasing such patients' level of risk of developing drug addiction to tramadol.

Thirdly, some of the subjects demonstrated poor knowledge of the adverse effects of NOAs. For instance, some of them mentioned addiction, tolerance, euphoria, and hallucination as adverse effects of NOA, meanwhile NOAs are not known to have addictive or psychedelic effect [12, 13]. Furthermore, the most commonly prescribed drugs among the respondents were ibuprofen, diclofenac, and paracetamol. Diclofenac and Ibuprofen are popularly known to cause drug-induced peptic ulcer [14]; possibly, some of these respondents may not know of this adverse effect.

Fourthly, some of the subjects in this present study had poor knowledge about the route of administration of NOAs. It is noteworthy that some of them highlighted some wrong routes of administration such as "spray," "epidural," "intra-vaginal," and "intra-capsular," to mention a few.

Based on the above findings, authors conclude that the surveyed clinical practitioners in this present study demonstrated inadequate knowledge of the pharmacology of NOAs. Authors would like to recommend that continual medical education (CME) programs (such as workshops, and seminars) on the use of NOAs should be organized for this population group. By doing so, their knowledge will be updated on the use of these drugs in patient management; hence improving the quality of services they render to the sick.

ACKNOWLEDGMENT

Authors declare that they have no competing interest regarding this study.

ABSTRACT

Overweight and obesity are on the increase worldwide and the adolescent population is of special concern. Methods of assessing overweight and obesity are being explored but neck circumference has not been widely investigated in adolescents. Objective: This study aimed at assessing neck circumference as a simple screening tool for overweight and obesity among Nigerian adolescents. Study group and Methods: A cross sectional survey was conducted among 897 adolescents aged 10-19 years in urban Lagos, using a stratified, multistage sampling method. Overweight and obesity were defined using the criteria by the United States Center for Disease Control. Student t test was used for continuous data and Pearson correlation coefficient for exploring the relationship

^{*} Corresponding Author's Email: eden_igbafe@yahoo.com.

between neck circumference and other variables. Receiver operating characteristic analysis was used to evaluate optimal neck circumference cutoffs for overweight or obesity. Results: 64 adolescents (7.1%) were overweight while those with obesity were 33 (3.7%). Neck circumference was positively correlated with age and Body Mass Index. There were significant differences in the neck circumferences of those that were overweight or with obesity compared to those with normal weight. The cutoff ranges for overweight/obesity per adolescent period were 33.95 to 36.95cm in males and 31.05 to 33.40cm in females. Sensitivities were 70-96.6% while specificities were 60.2-87.7%. Conclusions: Neck circumference is a simple and reliable tool which could be used to screen for overweight and obesity in Nigerian adolescents.

INTRODUCTION

Overweight and obesity have become major public concerns worldwide [1] as they are being reported increasingly in developed and recently in developing countries [2] including Nigeria [3]. The adolescent population is of special concern because the health and mortality risks of these phenomena are higher when developed during this period compared to development in adulthood [4]. Therefore, screening and detection of adolescent overweight and obesity are important as there are strategies to manage them [4]. Furthermore, a preliminary step towards curtailing the obesity epidemic is to provide monitoring tools that are cost effective, quick, easy to use, and acceptable to both recipients and health care practitioners [1].

Weight status is currently being described using the body mass index (BMI) [5], which in children and adolescents, varies with age and gender [5]. It has however been criticized for its reduced ability to describe central fat with which the greater health risks of overweight and obesity are associated [6] and for its time consuming derivation [7], amongst other things. Hence, simple, acceptable, quick and reliable methods of assessing overweight and obesity are being explored [7].

The neck is an easily accessible part of the body and its measurement is simple, quick and inexpensive [1, 7]. Limited studies have been documented on the use of neck circumference (NC), to identify overweight and obesity [1, 7, 8]. However, NC has not been investigated as a screening tool for overweight and obesity in Nigerian adolescents. The aim of this study is to determine the usefulness of neck circumference as a screening tool for overweight and obesity among Nigerian adolescents.

OUR SURVEY

A cross sectional survey was conducted from March to July 2013, among a representative sample of 897 adolescents aged 10-19 years in urban Lagos, using a stratified, multistage sampling method. Metropolitan Lagos is said to have captured 36.8% of Nigeria's urban population [9] making it the nation's largest urban population. The multistage sampling method included simple random, stratified random, systematic random and probability proportional-to-size (PPS) sampling techniques employed in the different stages.

Ethical and administrative approvals were obtained from the Health Research and Ethics Committee of the Lagos University Teaching Hospital and the Lagos State Ministry of Education, respectively.

Only those who satisfied the inclusion criteria were enrolled for the study. These criteria included subjects in the age group 10-19 years, consent from parents or guardians, assent from subjects and completed questionnaires. Exclusion criteria applied were possession of neck masses or deformities and history of or features suggestive of chronic ill health such as sickle cell disease and poorly controlled bronchial asthma.

Measurements

The selected study participants had their anthropometries determined. Trained volunteer measurers took the anthropometric measurements which included weight, height and neck circumference. These three measurements were taken using standard methods, according to the protocols recommended in the International Standards for Anthropometric Assessment published [10].

Body Mass Index (BMI)

BMI was calculated using a standard formula:

$$\text{BMI} = \text{Weight (kg)} / \text{height}^2 (\text{m}^2) \text{ in kg/m}^2$$

This was done with the aid of the Children's BMI Tool for Schools [11], a software produced by the United States Centre for Disease Control. Adolescents with BMI at 85th to just below the 95th percentile were said to be with overweight while those with BMI at 95th percentile and above were with obesity.

Data Analysis

The data was analyzed using the statistical software package SPSS Version 17.0. Mean with standard deviation were generated as necessary for age and gender specific anthropometric indices. Tests of statistical significance included Student's t test for continuous data and chi-square test for discrete data. Pearson correlation coefficient was used to explore the association between neck circumference and other continuous variables.

Receiver operating characteristic (ROC) analyses were used to determine the predictive validity of neck circumference and also evaluate optimal cut off values for adolescents with overweight and obesity in the different age categories. ROC curves assess the ability of a screening test to diagnose an outcome correctly, with reference to a gold standard.

The essentials of ROC analysis include [12] the sensitivity, specificity, the positive (PPV) or negative predictive value (NPV) of the test, the likelihood ratio for a positive (LR+) or a negative (LR-) test, the ROC curve and its area under the curve (AUC). Sensitivity and

specificity are usefully combined in likelihood ratios. A high likelihood ratio for a positive result and a low likelihood ratio for a negative result indicate that a test is useful [12]. The ideal test would have an AUC of 1 while a random guess would have an AUC of 0.5. Hence, AUC values closer to 1 indicate a test is useful. Probability values less than 0.05 were accepted as statistically significant.

FINDINGS

Eight hundred and ninety-seven students, selected from public and private schools, participated in the study. Of these, ninety seven were either overweight or obese based on defined BMI criteria [11], making the overall prevalence of overweight and obesity 10.8%. Prevalence of obesity was 3.7% (thirty-three) while that of overweight was 7.1% (sixty-four).

Body Mass Index Categories in Relation to Gender (See Table 1)

This shows the overall prevalence of overweight and obesity along gender lines.

Table 1. Body mass index categories in relation to gender

Gender	BMI Percentile		Total
	<85 th Percentile	≥85 th Percentile	
Female	474 (87.13%)	70 (12.87%)	544 (100%)
Male	326 (92.35%)	27 (7.65%)	353 (100%)
Total	800 (89.2%)	97 (10.8%)	897 (100%)

Chi-square test (χ^2): 6.046, p value = 0.014.

Table 2. The neck circumference of study participants in relation to age and gender

Age (years)	Male		Female		t	p
	n	Mean ($\pm$ SD) cm	n	Mean ($\pm$ SD)cm		
10	12	30.49 (2.50)	12	30.50 (1.76)	-0.021	0.98
11	23	29.68 (2.86)	39	30.15 (2.81)	0.436	0.67
12	48	30.80 (2.34)	83	30.80 (2.58)	-1.014	0.316
13	48	31.68 (2.87)	88	30.86 (2.18)	-1.046	0.301
14	44	32.19 (2.78)	84	30.48 (2.09)	-3.306	0.002
15	60	33.30 (2.80)	109	31.34 (2.33)	-4.042	<0.001
16	51	34.11 (2.58)	66	31.17 (2.23)	-6.454	<0.001
17	37	35.09 (2.55)	34	31.37 (2.14)	-7.496	<0.001
18	20	34.87 (2.04)	20	31.32 (2.22)	-6.697	<0.001
19	10	36.85 (3.83)	9	31.94 (3.27)	-2.708	0.027
All	353	32.77 (3.17)	544	30.93 (2.35)		

Neck Circumference Range in Relation to Age and Gender (See Table 2)

The mean NC ($\pm$ S.D) for all males 32.77(3.17) cm while that for all females was 30.93(2.35) cm. From the ages of 10 to 13 years, the mean NC values in males and females were not significantly different. However, from the age of 14 to 19 years, the mean NC values of males were significantly higher than those of females ($p < 0.001$ to $p = 0.027$).

Neck Circumference Range in Relation to Age, Gender and Body Mass Index Categories (See Table 3)

Table 3 shows that the mean NC ($\pm$ S.D) of all adolescent males with BMI <85th percentile was 30.05(2.03) cm while in those with BMI $\geq$ 85th percentile it was 35.5(3.09) cm ($p = <0.001$). For the adolescent females, these were 29.23(1.95) cm and 33.76(2.54) cm respectively ($p = <0.001$). Thus, there was a significant difference in the NC of subjects in the two BMI categories in both genders.

Table 3. Neck circumference of study participants in relation to age, gender and body mass index categories

Age (years)	Males				Females			
	<85 th percentile		$\geq$ 85 th percentile		<85 th percentile		$\geq$ 85 th percentile	
	Mean ($\pm$ SD)cm n		Mean ($\pm$ SD)cm n		Mean ($\pm$ SD)cm n		Mean ($\pm$ SD)cm n	
10	30.10 (1.49)	10	32.55 (2.05)	2	29.26 (1.72)	8	32.95 (1.98)	4
11	29.50 (2.92)	21	31.60 (0.42)	2	29.28 (2.06)	31	33.61 (2.59)	8

18	34.86 (2.04)	20	--		31.04 (2.17)	18	33.75 (0.35)	2
19	36.85 (3.83)	10	--		31.94 (3.27)	9	--	
All	30.05 (2.03)	326	35.50 (3.09)	27	29.23 (1.95)	474	33.76 (2.54)	70

t test: -7.328, $p < 0.001$ (Males)

t test: -10.824, $p < 0.001$ (Females)

Correlation Studies

There was significant positive correlation between neck circumference and BMI ($r = 0.538$, $p < 0.001$). When split along gender lines and adolescent periods the correlation is shown in Table 4.

Table 4. Correlation between neck circumference and body mass index in relation to gender and period of adolescence

Age group	Male r	p value	Female r	p value
10 – 13 years	0.556	<0.001	0.673	<0.001
14 – 16 years	0.698	<0.001	0.650	<0.001
17 – 19 years	0.515	<0.001	0.554	<0.001

Optimal Cutoff Values of Neck Circumference For Overweight/Obesity

Table 5 shows the AUC and NC cutoff values with their corresponding sensitivities and specificities in the males per adolescent period. Using the ROC statistical maneuvers, the optimal NC cutoff for overweight and obesity in a boy in middle adolescence is 35.85cm with a sensitivity of 77.8% and specificity of 87.7%. The positive likelihood ratio (LR+) of 6.3, indicates that a boy of 14-16 years with a NC greater than 35.85cm is 6.3 times more likely to be with overweight or obesity than a boy of the same age with NC value less than or equal to 35.85cm. A negative likelihood ratio (LR-) of 0.2 means that a negative result (≤ 35.85 cm) is 0.2 times as likely for a 14-16 year old boy who is overweight or obese as one who is normal weight. Table 6 shows the AUC and NC cutoff values with their corresponding sensitivities and specificities in the females per adolescent period. As was done in the males, the optimal NC cutoff for overweight and obesity in a girl in early adolescence is 31.05cm with a sensitivity of 96.6% and specificity of 65.8%. Also, the LR+ of a girl of in this group (10-13 years) with a NC of > 31.05 cm is 2.8 while LR- is 0.05. Furthermore, though the sensitivities of the proposed cutoff values decrease as age increases, their LR+ are almost the same or increase with a corresponding decrease in LR-, indicating their usefulness.

Table 5. Optimal neck circumference cutoff values for high body mass index in males, their sensitivities and specificities per adolescent period

Age group n(n ⁰) (years)	AUC (95% CI)	Cutoff (cm)	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	LR+	LR-
10 – 13 131(13)	0.786 (0.660-0.911)	31.05	84.6	60.2	19.1	97.4	2.1	0.49
14 – 16 155(9)	0.888 (0.786-0.990)	35.85	77.8	87.7	28.1	98.5	6.3	0.25
17 – 19 67(5)	0.774 (0.623-0.926)	36.05	80	69.4	16.7	97.8	2.6	0.29

n(n⁰): total number (number with overweight/obesity), CI: Confidence Interval.

Table 6. Optimal neck circumference cutoff values for high body mass index in females, their sensitivities and specificities per adolescent period

Age group n(n ⁰) (years)	AUC (95% CI)	Cutoff (cm)	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	LR+	LR-
10 – 13 222(29)	0.877 (0.825-0.929)	31.05	96.6	65.8	29.8	99.2	2.8	0.05
14 – 16 259(31)	0.834 (0.760-0.908)	31.35	80.6	67.1	25.0	96.2	2.4	0.28
17 – 19 63(10)	0.802 (0.650-0.959)	32.90	70	84.9	46.9	93.7	4.6	0.35

n (n⁰): total number (number of adolescents with overweight/obesity), CI: Confidence Interval.

DISCUSSION

There has been a rising trend in the prevalence of adolescent overweight and obesity globally [13]. This poses major public health concerns because of the adverse associated outcomes such as psychosocial [14], health and socioeconomic consequences [15]. Therefore,

the importance of providing tools that screen and detect these epidemics cannot be over emphasized [1].

Various methods are available to assess body fat and thereby detect overweight or obesity, but for epidemiological purposes, body mass index (BMI) skin-fold thickness measurement, bioelectrical impedance analysis (BIA), waste circumference and waist-hip ratio are some which have been recommended [5, 16 17].

BMI, derived from weight and height, is currently the best available anthropometric estimate of fatness for public health purposes [18] and was used as the gold standard for overweight and obesity in this study. It has the advantages of being simple, easily available, inexpensive, with a high degree of reproducibility but limited because it does not discriminate between fat and muscle, does not correlate with central fat (the index of obesity related health risks) [18] and its derivation is time consuming [7].

BIA, a non-anthropometric tool, is relatively inexpensive (when compared with other non-anthropometric methods) and easy to use [16], but its results are influenced by the environment, ethnicity, phase of menstrual cycle and underlying medical conditions. Hence its measurements should be validated for specific ethnic groups, populations and conditions prior to its use [19].

Waist circumference (WC), an index of central fat distribution, also said to be the best simple anthropometric measure of total body fat and more sensitive than BMI [17] has limited wide-spread acceptance because there is no agreement about landmarks, when to measure it, and what it means [20]. Furthermore, it could be culturally or environmentally problematic as clothes have to be removed for it to be measured accurately [1].

Neck circumference (NC), an index of central fat distribution, was found to be independently related to cardiovascular risk factors in obese adults [21], reported to be a simple and time-saving tool for screening and identifying overweight and obese adults [7] and children [1]. Though said to correlate less with BMI than WC [1, 8], NC, unlike WC, has agreed land marks, is easily accessible in the neck, and clothes don't need to be removed for it to be measured accurately. Lastly, in adolescents, NC was found to show very good inter and intra-rater reliability [22]. Multiple measurements are not required for precision and reliability.

In Nigeria, there's a dearth of studies on indices of central fat in the adolescent population and none has explored the usefulness of NC as a screening tool for overweight and obesity in adolescents, hence the relevance of this study.

This study confirms the presence of adolescent overweight and obesity in Nigeria, albeit at lower rates when compared with the western world and Mediterranean region, consistent with the review stating that countries in sub-Saharan Africa have the lowest prevalent rates of adolescent overweight and obesity [13]. This is because the speed of this epidemic is said to be slower in less economically developed countries predominant in sub-Saharan Africa as a result of the less rapid changes in diet and activity associated with the lower income in these countries [13].

In this study, the mean NC of males and females aged 10 to 13 years were not significantly different, but from the age of 14 to 19 years, the mean NC of males was significantly higher than that of the females. This is consistent with similar studies in children and adolescents in the United States of America [1] and Turkey [8] and may be explained by the fact that male sex hormones (androgens) are associated with deposition of fat in the upper body, of which the neck region is a part of [6]. Female sex hormones on the other hand are

associated with an increase in lower body fat which includes the thighs and gluteal region [6]. Also, pubertal changes in boys, marked by the appearance of secondary sexual characteristics, are usually as a result of increased androgenic secretion from the gonads which begin to be seen at about 11 to 12 years of age [23]. These androgens also cause laryngeal and pharyngeal enlargement in males [24]. As the androgenic secretions continue to increase in the latter adolescent years, it is not surprising that its effect on the neck was evident in the increasing neck circumference of the male subjects in this study, throughout their mid- and late adolescent years.

BMI was found to significantly correlate positively with NC, as was seen in other studies [1, 8]. The fact that NC was significantly different in the two BMI categories studied in both genders (normal and high BMI) indicates that it would do well as marker for overweight and obesity.

This study proposed NC cutoff values for overweight and obesity per period of adolescence, and not per singular age group, as were seen in similar studies carried out in areas of higher overweight/obesity prevalence [1, 8]. This may be useful in places with relatively low prevalence of overweight and obesity so that larger numbers of overweight or obese people are available to evaluate optimal cutoff values, as opposed to the fewer numbers or none that may be available when evaluated per singular age. Secondly, the larger groupings per adolescent period means that fewer cutoff values need to be remembered by a busy clinician who may not have time to refer to a chart which would be a necessity if the cutoff values were provided per singular age group.

ROC analysis routinely provides predictive values for the diagnostic test being evaluated, being NC in this instance. The positive predictive values of NC were low, while the negative predictive values were high. These values depend on disease prevalence and are not unwavering characteristics of the diagnostic test that is being evaluated [25]. Hence, they could be misleading in an area of relatively low prevalence such as Nigeria. A more clinically useful measure is the Likelihood Ratio which is independent of prevalence [25].

With the high sensitivities and less remarkable specificities of the proposed NC cutoff values, along with their high positive likelihood ratios and low negative likelihood ratios, NC can serve as a good screening tool for overweight and obesity in Nigerian adolescents. Further evaluation of those with a positive test based on the NC value can then be carried out with more specific tests of overweight and obesity.

A limitation of this study is that its findings may not be extended to adolescents outside the school community like those already employed or in other institutions of learning.

CONCLUSION

This study has demonstrated that neck circumference is a useful screening tool for obese and overweight adolescents. It is simple and cost effective and so envisaged to be beneficial in primary health care settings. Hopefully this picks-up potential candidates for the two morbidities and avert the more sinister associated complications.

ACKNOWLEDGMENTS

The authors will like to thank all the students that participated in this research, their parents and the volunteer measurers. Special thanks also go to certain individuals who supported this research financially namely Air Vice Marshall Nicholas Spiff (Rtd), Air Commodore Simon Okwuokei (Rtd) and Air Commodore Adebayo Bolajoko (Rtd).

The authors declare that they have no conflict of interest. Informed consent was obtained from the parent/guardian of each participant involved in this study. Assent was obtained from each participant. This study was conducted in accordance with the 1964 Declaration of Helsinki and its subsequent amendments.

ABSTRACT

Triglyceride-to-high-density lipoprotein cholesterol (TG/HDL-C) ratio is a cost-effective tool to predict and identify insulin resistance and cardiometabolic risk in overweight/obese children and adolescents. The present study described the pattern and distribution of TG/HDL-C ratio as well as its use in determining the prevalence of insulin resistance in overweight/obese adolescents. *Methods:* In this school-based cross-sectional study, the serum lipid levels (total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), triglyceride (TG), and low density lipoprotein cholesterol (LDL-C) of overweight/obese and normal weight adolescents were measured. The TG/HDL-C ratio was calculated for subjects and controls. Insulin resistance was defined by serum TG/HDL-C ratio greater than 2.27. *Results:* In the overweight/obese participants, 53.1% and 38.8% were in middle and upper tertiles of TG/HDL-C concentration ratios, respectively. The mean TG/HDL-C ratios was higher in overweight/obese than normal weight participants; 1.92 ± 0.64 (95% CI = 1.74-2.10) versus 1.68 ± 0.31 (95% CI =

1.59-1.77); p-value < 0.05. The prevalence of insulin resistance as defined by TG/HDL-C > 2.27 was significantly higher in overweight/obese than normal weight adolescents; 35.4% (95% CI = 28.6-42.2) versus 12.2% (95% CI = 7.5-16.9); Odds ratio (OR) = 4.0. *Conclusion:* Clinicians can apply TG/HDL-C ratio to the standard lipid screening in order to identify overweight/obese adolescents with increased risk of insulin resistance and cardiometabolic disorders.

INTRODUCTION

The triglyceride-to-high-density lipoprotein cholesterol (TG/HDL-C) ratio reflects the association between triglyceride (TG) and high density lipoprotein cholesterol (HDL-C), depicting the balance between atherogenic and protective lipoproteins [1]. TG/HDL-C ratio has a good correlation with LDL particle size in children and adolescents [2]. This lipid ratio has been found to be a useful marker in detection of early functional and morphological vascular changes as well as nonalcoholic fatty liver disease (NAFLD) in paediatric population [3, 4]. The results of some studies indicate that elevated TG/HDL-C ratio in children and adolescents is associated with increased risk of insulin resistance, high blood pressure, metabolic syndrome and NAFLD [4-7]. In a study in China, it was concluded that TG/HDL-C ratio has a discriminatory power in detecting potential metabolic syndrome in the paediatric age group [8]. In the same study, the authors stated in their conclusion that TG/HDL-C ratio was a better index than homeostasis model assessment insulin resistance (HOMA-IR) for screening for metabolic syndrome in obese children and adolescents. Urbina et al. [9] demonstrated that elevated TG/HDL-C ratio was an independent determinant of arterial stiffness in adolescents and young adults, suggesting that the use of TG/HDL-C ratio may also be helpful in identifying young adults requiring intervention to prevent arteriosclerotic cardiovascular disease. In a study involving Spanish children, aged 2-17 years, it was demonstrated that TG/HDL-C ratio > 2 is an effective and relatively cheap biomarker to identify the early stage of potential metabolic syndrome in overweight/obese paediatric population at any age and pubertal status [10]. Therefore, some researcher have recommended that TG/HDL-C ratio should be routinely determined from traditional serum lipid levels to assess atherogeneity of dyslipidaemias which is critical for prevention of cardiometabolic diseases [4, 5].

The results of several studies have demonstrated that TG/HDL-C ratio is a useful surrogate for insulin resistance in the paediatric age group [3, 6, 11, 12]. The interest in TG/HDL-C ratio as a tool for estimating insulin resistance was because of ease of measurement in routine clinical settings and cost-effectiveness. Within this context, other components of insulin sensitivity indices such as insulin, C-peptide, leptin, cytokines and free fatty acids are more expensive to measure. In resource-limited countries, simple affordable screening tool is an attractive option. There are lines of evidence showing that TG/HDL-C ratio is a relatively simple cost-effective way to identify apparently healthy insulin-resistance children and adolescents with increased cardiometabolic risk [5, 13]. Various cutoff points of serum TG/HDL-C ratio have been used as a surrogate in different studies to define insulin resistance in children and adolescents. In this regard, Pacifico et al. [4] used ≥ 1.98 and Hannon et al. [15] used ≥ 3.0 as definitions, respectively. In two separate studies, serum TG/HDL-C ratio greater than 2.27 was used in identifying overweight/obese children and

adolescents with insulin resistance [7, 14]. The results of a study in Malaysian children, aged 9 to 16 years, revealed that children with insulin resistance had a significantly higher TG/HDL-C ratio than those without insulin resistance [16]. In the same report, the authors stated that the odds of having insulin resistance was about 2.5 times higher for those in the upper tertile of TG/HDL-C ratio compared with those in the two lower tertiles. Di Bonito et al. [5] demonstrated that TG/HDL-C ratio ≥ 2.0 is associated with several cardiometabolic risk factors and preclinical signs of cardiac abnormalities in a group of Caucasian children and adolescents, suggesting that this lipid ratio may also predict insulin-resistance-mediated organ damage. Inter-ethnic differences in muscle, liver and abdominal fat partitioning has been demonstrated, suggesting that the degree of insulin resistance may be different for the same body mass index, depending on ethnicity [17, 18]. It has been reported that TG/HDL-C ratio ≥ 2.2 was significantly associated with impaired glucose tolerance (IGT) in children and adolescents, reflecting its usefulness in identifying overweight/obese individuals at risk of IGT [19] and future type 2 diabetes [20, 21]. To the best of our knowledge, there is no published report on the pattern, distribution and use of TG/HDL-C ratio as a surrogate for identifying insulin resistance in overweight/obese Nigerian children and adolescents. The aim of the present study is to describe the pattern and distribution of TG/HDL-C ratio as well as its use in determining the prevalence of insulin resistance in overweight/obese adolescents.

OUR STUDY

This was a school-based cross-sectional study involving an urban secondary school in Egor Local Government Area (LGA) of Edo State, Nigeria. The study was conducted over one-month period, 1st to 30th June, 2016. Ethical clearance certificate was obtained from Research and Ethics Committee of the College of Medical Sciences, University of Benin, Benin City. The administrative head of the school and the ministry of education gave permission for the conduct of the study. Written informed consent was obtained from the parent(s)/caregiver of each of the study subjects. We obtained verbal consent from each of the participants and emphasized to them that their participation was entirely voluntary.

Study Group and Sampling Technique

In this study, the first secondary school in a list of alphabetically arranged private secondary schools in Egor LGA was selected. The list of private secondary schools was obtained from the Edo State Ministry of Education [22]. Thereafter, students within the age group of 10-16 years were randomly selected. Each of the selected students was given a written note explaining the nature of the study as well as a questionnaire to be completed by their parent(s). The subjects (high BMI, $\geq 85^{\text{th}}$ percentile) and controls (normal BMI, 5^{th} to $< 85^{\text{th}}$ percentile) were matched for age and gender. The socio-economic status and ethnicity of the subjects and controls were largely similar. Excluded from the study were students with positive history or obvious clinical evidence of hypothyroidism, liver disease, chronic kidney disease, Cushing syndrome, diabetes mellitus or who are on drugs such as corticosteroids or oral contraceptives.

Anthropometric Measurements

Following a standard procedure [23] the height was measured to the nearest 0.1 cm, using a Holtian portable anthropometer and the weight was measured to the nearest 0.1 kg, using a Seca Scale Balance with the subject in light clothing and bare foot. If a duplicate measurement differed by > 0.5 cm or > 0.5 kg respectively, a third measurement was performed and the average of the two closest measurements was recorded as the final value. To eliminate inter-observer error, all the anthropometric measurements were performed by one of the authors. The body mass index of each of the subjects was computed, using the standard formula [23]. The blood pressure of the participants was measured by one of the authors and steps were taken to minimize errors.

Blood Sample Collection and Serum Lipid Profile Analysis

Venous blood sample was collected after the details of the intended procedure was explained to the participants. The participants maintained their usual dietary pattern within the past three days preceding the study. Following an overnight fast (at least 12-hour fast), 5ml of venous blood was collected into appropriate sample container without anticoagulant and stored at 8°C. After one hour, all samples were centrifuged at 3000rpm for 15 minutes and the serum aliquots were stored at -20°C until assayed. The serum concentrations of total cholesterol (TC), high-density lipoprotein-cholesterol (HDL-C) and triglycerides (TG) and low-density lipoprotein-cholesterol (LDL-C) were determined, using automated analyzer with commercially available kits and following strictly the manufacturer's instructions throughout the assay procedures.

Definitions

TG/HDL-C ratio was calculated as TG(mg/dl) divided by HDL-C (mg/dl). The participants were grouped into tertiles based on their serum TG/HDL-C concentration ratios as follows: lower tertile < 1.2; middle tertile 1.2 to < 2.0; and upper tertile ≥ 2.0 [6]. Participants with TG/HDL-C ratio in the upper tertile were considered as having high TG/HDL-C ratio [5, 6]. Serum TG/HDL-C ratio greater than 2.27 defined insulin resistance [7, 14]. High serum triglyceride concentrations was defined as triglyceride ≥ 130 mg/dl (for children ≥ 10 years old) and low HDL-C concentration as < 40mg/dl, according the criteria proposed by National Heart, Lung and Blood Institute (NHLBI) in 2011 [24]. Normal weight, overweight and obesity were defined as BMI between 5th to < 85th, 85th to < 95th and $\geq 95^{\text{th}}$ percentiles, respectively.

Table 1. Characteristics of the subjects (overweight/obese) and controls (normal weight) according to gender

Characteristics	Subjects Male	Controls Male	t-statistic (p-value)	Subjects Female	Controls Female	t-statistic (p-value)
Mean weight (kg)	52.3 ± 6.4	39.1 ± 7.8	9.158 (< 0.001)	40.6 ± 5.2	36.3 ± 8.4	3.047 (< 0.01)
Mean height (cm)	149.3 ± 6.8	142.4 ± 6.6	5.097 (< 0.01)	146.8 ± 7.3	140.3 ± 5.6	4.945 (< 0.01)
Mean BMI(kg/m ²)	27.32 ± 72	16.8 ± 2.15	9.800 (< 0.001)	28.7 ± 3.3	17.5 ± 3.50	16.300 (< 0.001)
Mean WC (cm)	83.2 ± 4.9	68.8 ± 4.1	15.777 (< 0.001)	88.9 ± 5.2	69.1 ± 6.7	16.342 (< 0.001)
Mean HC (cm)	90.3 ± 10.6	70.8 ± 8.8	9.908 (< 0.001)	102.3 ± 8.7	72.5 ± 8.6	17.052 (< 0.001)
Mean WC/HC ratio	0.90 ± 0.08	0.85 ± 0.05	3.710 (< 0.001)	0.86 ± 0.05	0.80 ± 0.06	5.378 (< 0.001)
Mean SBP (mmHg)	107.3 ± 10.2	103.5 ± 9.9	1.871 (> 0.05)	105.0 ± 9.4	101.5 ± 9.3	1.853 (> 0.05)
Mean DBP(mmHg)	70.0 ± 6.7	63.6 ± 8.8	4.051 (< 0.001)	65.7 ± 9.1	62.1 ± 9.6	1.905 (> 0.05)
Mean TC (mg/dl)	136.3 ± 26.6	124.2 ± 23.8	1.652 (> 0.05)	141.0 ± 25.8	133.2 ± 20.9	1.243 (> 0.05)
Mean HDL-C(mg/dl)	37.0 ± 5.2	37.2 ± 4.6	0.132 (> 0.05)	38.1 ± 6.1	37.1 ± 5.3	0.655 (> 0.05)
Mean TG (mg/dl)	101.8 ± 27.2	90.3 ± 25.6	1.414 (> 0.05)	102.5 ± 23.7	95.5 ± 22.7	1.129 (> 0.05)
Mean LDL-C(mg/dl)	68.5 ± 24.2	65.7 ± 25.8	0.363 (> 0.05)	76.7 ± 20.2	73.1 ± 18.8	0.690 (> 0.05)

WC = Waist circumference; HC = Hip circumference; SBP = Systolic blood pressure; DBP = Diastolic blood pressure.

Statistical Analysis

The data were collated and entered into an Excel spread sheet. Accuracy of the data entered was double checked. Subsequently, data were analysed, using Microsoft Excel and SPSS (Statistical Package for Social Sciences) version 20.0. The descriptive statistics reported are mean, standard deviation, confidence intervals, tertiles and percentages. Differences between means were tested with t-test and proportions were tested using Z-test. Significant p-values were set at < 0.05.

FINDINGS

A total of 98 (49 subjects and 49 controls) students were investigated. There were 29 girls and 20 boys in each of the two groups. The mean age of the participants was 12.1 ± 1.2 years. The characteristics of subjects and controls are displayed in Table 1. Overweight/obese participants had a significantly higher mean BMI and waist circumference.

As shown in Table 2, 38.8% of overweight/obese participants were in the upper tertiles of TG/HDL-C concentration ratio. The mean TG/HDL-C ratio was higher in overweight/obese than in normal weight adolescents; 1.92 ± 0.64 (95% Confidence Interval, CI = 1.74-2.10) versus 1.68 ± 0.31 (95% CI = 1.59-1.77); t-statistic 2.362, $p < 0.05$. Table 3 shows that the prevalence of insulin resistance (TG/HDL-C ratio > 2.27) was 35.4% (95% CI = 28.6-42.2) and 12.2% (95% CI = 7.5-16.9) in overweight/obese and normal weight adolescents, respectively; Odds ratio (OR) = 4.0. When TG/HDL-C ratio ≥ 3.0 was applied as cutoff point for insulin resistance, only two (4.1%) overweight/obese but none in normal weight group demonstrated insulin resistance. In both overweight/obese and normal weight groups none had serum triglyceride level equal or greater than 130 mg/dl.

Table 2. Frequency of tertiles of TG/HDL-C concentration ratios in overweight/obese and normal weight subjects

Tertiles of TG/HDL-C Ratio	Normal weight (n = 49) No (%)	Overweight/obese (n = 49) No (%)	Z-statistic (p-value)
Lower (< 1.2)	9(18.4)	4(8.2)	1.504(>0.05)
Middle (1.2 to < 2.0)	23(46.9)	26(53.1)	0.615(>0.05)
Upper (≥ 2.0)	17(34.7)	19(38.8)	0.421(>0.05)

TG = Triglyceride; HDL-C = High density lipoprotein cholesterol.

Table 3. Prevalence of insulin resistance in overweight/obese and normal weight participants based on TG/HDL-C ratio greater than 2.27

Category of participant	Prevalence of insulin resistance (TG/HDL-C ratio > 2.27) Number Percent	Z-statistic (p-value)
Normal weight (n = 49)	6 12.2	
Overweight/obese (n = 49)	17 35.4	2.802(<0.01)
Total (N = 98)	23 23.5	

TG = Triglyceride; HDL-C = High density lipoprotein cholesterol.

DISCUSSION

Nearly every four out of ten of our overweight/obese adolescents demonstrated upper tertile TG/HDL-C concentration ratios (≥ 2.0) which is considered elevated. Other investigators have reported a similar finding [6]. Considering the report of Di Bonito et al. [5], this finding is worrisome. Di Bonito et al. [5] demonstrated that TG/HDL-C ratio ≥ 2.0 is associated with increased risk of cardiometabolic disorders in a group of Caucasian children and adolescents. In the same study, they found an association with preclinical signs of cardiac abnormalities. The public health implication is that TG/HDL-C ratio in upper tertile constitutes a non-communicable healthcare burden because it may also predict insulin-resistance-mediated organ damage [5]. In addition, some studies have shown that an elevated TG/HDL-C ratio (≥ 2.0) identified the onset of metabolic alterations related to metabolic syndrome (MetS), such as decreased insulin sensitivity and altered lipid profile [5, 10, 25]. The elevated TG/HDL-C ratio found in the present study was mainly due to low serum HDL-C concentrations as none of the participants, in both subjects and controls, had serum triglyceride level in the abnormal range (i.e., ≥ 130 mg/dl in individuals ≥ 10 years old), using the criteria proposed by National Heart, Lung and Blood Institute (NHLBI) in 2011 [24]. The public health implication is that specific dietary modification capable of increasing serum HDL-C level is indicated in our adolescent population.

As in other reports [6], the mean TG/HDL-C concentration ratio was statistically significantly higher in overweight/obese than normal weight adolescents in this study. Further confirming that overweight/obesity is a risk factor for abnormal TG/HDL-C ratio in adolescents.

We found a 4-fold greater odd of elevated TG/HDL-C ratio (>2.27) for overweight/obese than normal weight adolescents. In the present study, as in others [7, 14], TG/HDL-C ratio greater than 2.27 was considered a surrogate for insulin resistance. Based on this criteria, prevalence of insulin resistance was statistically significantly higher in overweight/obese than in normal weight group. Our finding is in consonance with previous reports [6, 13, 19]. Adolescents with such abnormal lipid ratio profile are at increased risk of exhibiting impaired glucose tolerance and may develop type 2 diabetes in future [20, 21]. It has been documented that when insulin sensitivity is impaired, compensatory hyperinsulinaemia is produced. Over time, pancreatic beta cell dysfunction occurs, promoting development of type 2 diabetes [25]. Within this context, TG/HDL-C ratio is a useful clinical tool for identifying adolescents at risk of MetS and low insulin sensitivity [5, 26]. Some pathophysiologic mechanisms have been proposed to explain the link between obesity and insulin resistance. Obesity results in proinflammatory state, starting in metabolic cells (adipocyte, hepatocyte, or myocyte). This is followed by recruitment of macrophages with subsequent release of inflammatory cytokines that predispose toward insulin resistance [27]. Chen et al. [28] have demonstrated that myostatin, a novel skeletal muscle-derived secretory factor has a strong relationship with obesity-associated insulin resistance. A higher ratio of TG/HDL-C implies a poor health status not only because the amount of fat in circulation is larger but also because the amount of healthy cholesterol in circulation is lower. Cardiometabolic risk factors tend to precede the development of atherosclerosis in obese children and adolescents [29]. Therefore, lifestyle modification is required in adolescents with TG/HDL-C concentration ratio > 2.27 . When a higher cutoff point of TG/HDL-C ratio of ≥ 3.0 was applied, the frequency of insulin

resistance was nearly 9 times lower in overweight/obese adolescents, suggesting that TG/HDL-C ratio > 2.27 was a more appropriate cutoff point in the paediatric age group.

Strengths and Weaknesses of the Study

The strength of the study is that the subjects and controls were derived from a single well defined source population. In addition, matching increased the statistical precision of estimates, thereby allowing smaller sample size. The weakness of the study was that the study population was derived from a single school, making it possible that the sample was not representative of adolescents in the source population. Despite this limitation, it provided baseline epidemiological data (the first among Nigerian adolescents) on the subject and could serve as an initial point for future study.

CONCLUSION

In conclusion, clinicians can apply TG/HDL-C ratio to the standard lipid screening in order to identify overweight/obese adolescents with increased risk of insulin resistance and cardiometabolic disorders.

CONFLICT OF INTEREST

We have no conflict of interest in this study.

PSEUDOHYPOPARATHYROIDISM: A RARE CAUSE OF HYPOCALCAEMIA

***Alphonsus N. Onyiriuka*, MBBS, FMCPaed
and Victor A. Esedume, MBBS***

Endocrinology and Metabolism Unit, Department of Child Health,
University of Benin Teaching Hospital, Benin City, Nigeria

ABSTRACT

Pseudohypoparathyroidism (PHP) is a rare heterogeneous group of disorders due to genetic defects in the hormone receptor adenylate cyclase system and whose common feature is end-organ unresponsiveness to parathyroid hormone. In all its forms, it is biochemically characterized by hypocalcaemia, hyperphosphataemia and elevated level of serum parathyroid hormone. In this report, we present a case of a 15-year-old Nigerian boy who had symptoms of both acute and chronic hypocalcaemia. He was referred to our hospital because of chest pain. Prior to his referral, he has had an episode of generalized tonic-clonic seizure. Further inquiry revealed history of muscle cramps and pain in the bones and joints. Anthropometric measurements revealed that weight, height and body mass index were all below the 5th percentile for age and gender. Trousseau's sign was positive in the patient. The laboratory findings include hypocalcaemia (serum calcium 0.18 mmol/L), hyperphosphataemia (serum phosphate 11.2 mmol/L), elevated parathyroid hormone (serum parathyroid hormone 7.8 pmol/L) level and normal serum magnesium (serum magnesium 0.72 mmol/L) level. Results of both the renal and thyroid function tests were normal. The diagnosis of PHP was delayed probably because of the rarity and heterogeneity of this clinical entity. Conclusion: Pseudohypoparathyroidism should be considered in any child or adolescent with persistent hypocalcaemia in the presence of elevated serum parathyroid hormone level, particularly if renal function tests and serum magnesium level are normal.

INTRODUCTION

Pseudohypoparathyroidism (PHP) is a rare heterogeneous group of disorders whose common feature is end-organ unresponsiveness to parathyroid hormone due to receptor or post-receptor defect [1]. In all its forms, it is biochemically characterized by hypocalcaemia, hyperphosphataemia and elevated serum parathyroid hormone (PTH) level [1]. The classification of PHP is based on the phenotype and cellular cyclic adenosine monophosphate (cAMP) response to exogenous parathyroid hormone administration. Phenotypically, some patients have the constellation of features of Albright Hereditary Osteodystrophy (AHO) which includes short stature, obesity, round face, shortened metacarpals and metatarsals and multiple hormonal resistances [1]. PHP is divided into two major groups, types I and II based on renal response to exogenous PTH administration [1]. Type I PHP is further subdivided into types Ia, Ib, Ic [1]. In patients with PHP types Ia and Ic features of AHO and multiple hormonal resistance are present. In contrast, patients with PHP types Ib and type II features of AHO and multiple hormonal resistance are absent [1]. Very recently, the EuroPHP Network proposed a novel nomenclature/classification from PHP to “inactivating PTH/PTHrP signalling disorder (iPPSD)” [2]. According to EuroPHP Network, the merits of the new terminology include (i) defines the common mechanism responsible for all diseases (ii) does not require a confirmed genetic defect (iii) avoids ambiguous terms like ‘pseudo’ and (iv) eliminates the clinical or molecular overlap between diseases. The authors concluded that the use of this nomenclature and classification will facilitate the development of rationale and comprehensive international guidelines for the diagnosis and treatment of iPPSDs [2].

The prevalence of PHP is largely unknown. The reported prevalence rates are 3.4 and 11 per million population in Japan and Denmark, respectively [3, 4]. An extensive search of the literature did not reveal any report on the subject from Nigeria. Thus, emphasizing the rare nature of this clinical entity.

A CASE STORY

A 15-year-old Nigerian boy referred to the Endocrinology and Metabolism unit, University of Benin Teaching Hospital (UBTH), because of persistent symptomatic hypocalcaemia despite treatment with oral calcium and vitamin D3. The patient was referred to UBTH from a private hospital because of recurrent chest pain of two years duration. The chest pain was sharp and retrosternal. In addition, he has recurrent muscle cramps, bone and joint pain which are aggravated by strenuous exercise and writing. In the past one month, the frequency of the muscle cramps, bone and joint pain has increased (coupled with the persistent hypocalcaemia) warranting referral to a paediatric endocrinologist. There is no history of disturbances of taste, smell, vision or hearing. Developmental milestones including pubertal development appear normal. He had an episode of seizure (probably hypocalcaemic) three years ago and no repeats since then. There was no history suggestive of chronic kidney or liver disease. The index patient is the second of three children (all boys) in the family. No family history of similar symptoms. He had an average academic performance. Physical examination revealed an apparently healthy-looking boy with weight 35.5 kg (<5th percentile), height 147 cm (<5th percentile) and body mass index 16.4 kgm⁻² (<5th percentile).

He had a positive Trousseau's sign and no shortening of metacarpals or metatarsals. He has no evidence of dental anomaly or subcutaneous calcification or cataract or moniliasis. His blood pressure was 80/60 mmHg. Examination of the body systems was unremarkable. The results of laboratory investigations showed that serum urea, electrolytes, creatinine as well as urinalysis were all normal. The results of his thyroid function tests were normal. Echocardiogram did not reveal any structural anomaly of the heart. His haemoglobin phenotype is AS. The initial laboratory findings are summarized in Table 1.

Table 1. Summary of initial biochemical results initial

Parameter	Results	Comments
Serum total calcium	0.18 mmol/L	Very low
Serum corrected calcium	0.13 mmol/L	Very low
Serum phosphate	11.2 mmol/L	Very high
Parathyroid hormone	7.8 pmol/L	High
Serum magnesium	0.72 mmol/L	Within normal limits
Serum albumin	4.2 g/L	Within normal limits
Serum alkaline phosphatase	411 μ U/L	Within normal limits
24-hour-urine calcium	1.92 mmol/24hrs	Low
Random blood glucose	5.1 mmol/L	Within normal limits

Table 2. Serial serum calcium and phosphate concentrations

Serial no	Serum total calcium mmol/L	Comments	Serum phosphate mmol/L	Comments
Test 1	0.93	Very low	1.87	High
Test 2	1.33	Low	2.00	High
Test 3	1.70	Low	2.84	Very high
Test 4	1.93	Low	2.13	High
Test 5	1.13	Very low	2.62	Very high
Test 6	1.86	Low	2.17	High

He had correction of the symptomatic hypocalcaemia using intravenous 10% calcium gluconate, followed by maintenance oral calcium but the hypocalcaemia persisted as shown in Table 2. In addition, his serum phosphate levels remained high.

We considered a clinical diagnosis of pseudohypoparathyroidism. Based on this diagnosis, we planned further laboratory investigation. In this regard, the Parathyroid Hormone Response Test with assay of urinary phosphate and cyclic adenosine monophosphate (cAMP) was planned. We were unable to perform this investigation because of inadequate laboratory facility in our hospital and financial constraint prevented using commercial medical laboratories outside. Oral calcium supplement was continued and the vitamin D was changed to oral 1 α -vitamin D (calcitriol).

DISCUSSION

In the index case, the presence of hypocalcaemia, hyperphosphataemia, elevated level of serum parathyroid hormone and normal serum magnesium level without evidence of underlying systemic disorder, such as chronic kidney disease suggested a diagnosis of pseudohypoparathyroidism. In addition, the absence of the phenotypic features of Albright Hereditary Osteodystrophy suggests a subtype diagnosis of PHP type Ib or type II [1]. The

clinical manifestations in our patient included an episode of seizure and recurrent episodes of muscle cramps, pain in the chest, bone and joints. The single episode of seizure may be related to severe hypocalcaemia at that time. His hypocalcaemic condition may have become clinically evident following the pubertal growth spurt, which is known to be associated with a relatively higher calcium requirements [5]. This clinical scenario in our patient is not surprising as Kabicek et al. [6] reported two cases of PHP in two adolescent boys; one with low back pain and the other with seizure. Although vitamin D deficiency with biochemical findings resembling PHP types I and II has been described [7], alone it is unlikely to cause significant hypocalcaemia as observed in our patient without a rise in alkaline phosphatase level. Our patient's serum alkaline phosphatase level was normal, thereby negating the diagnosis of vitamin D deficiency.

The etiologic diagnosis of the persistent hypocalcaemia was delayed for 2 to 3 years in our patient despite several medical consultations. This is not surprising as similar observation has been reported from Italy [5] and India [9]. In the case reported from India, the patient had symptoms of chronic hypocalcaemia for 10 years before diagnosis [9]. The difficulty in diagnosing PHP is due to its rarity as well as the varying phenotypic aspects. The clinical implication is that full biochemical investigation of calcium-phosphate metabolism is required in any child or adolescent with signs and symptoms of hypocalcaemia to avoid missed aetiological diagnosis. In this regard, it is imperative to always measure serum levels of calcium, phosphate, magnesium and parathyroid hormone. In addition, assessment of the renal function is required to exclude hyperphosphataemia secondary to chronic kidney disease [10]. Measurement of serum magnesium is important because low serum magnesium is known to impair both the secretion and function of parathyroid hormone [1].

We encountered some challenges in evaluation and management of the index case. Inadequate laboratory facility prevented us from performing the Parathyroid Hormone Response Test with assay of urinary phosphate and cAMP to distinguish between PHP types I and II and molecular studies (demonstration of the mutated G-protein) to confirm our diagnosis of PHP. The parents of the patient were experiencing difficulties procuring oral calcitriol, which is the preferred form of vitamin D for therapy. Despite this limitation, we are reasonably certain that the patient has PHP (with either types Ib or II being the likely subtype). It is possible that in future, if the novel classification proposed by EuroPHP Network [2] is adopted, more appropriate diagnosis could be achieved with less sophisticated laboratory investigations, particularly in resource-limited countries with inadequate laboratory facilities.

CONCLUSION

In conclusion, the learning point is that full biochemical investigation of calcium-phosphate metabolism is required in any child or adolescent with signs and symptoms of hypocalcaemia to avoid missed aetiological diagnosis. Pseudohypoparathyroidism should be considered in any child or adolescent with persistent hypocalcaemia associated with elevated parathyroid hormone level, particularly if serum magnesium level and renal function are normal.

ABSTRACT

Wheat stripe rust (SR), caused by the fungus *Puccinia striiformis* f. sp. *tritici* (*Pst*), is one of the most aggressive crop diseases worldwide that threatens global food security. In Argentina, the disease caused the worst epidemics in 2017 affecting about three million hectares. The occurrence of the epidemics was anomalous, as for 87 years there had not been disease outbreaks of this magnitude. We were able to relate the epidemics to the incursion of new exotic strains of *Pst* into the Argentine wheat-growing regions, where the majority of wheat varieties are susceptible to the disease. In addition, we estimated the impact and chemical control of the disease in the region. Average wheat yield losses were estimated at 3,700 kg ha⁻¹ (53%) in field trials conducted in the epidemic area with a maximum of up to 4,700 kg ha⁻¹ (70%) in the seven most susceptible varieties. This scenario represents a challenge for plant breeders, since the vast majority of wheat varieties are susceptible to the new *Pst* races. Fungicides showed to be highly effective in reducing SR intensity and yield losses, thus they have become the only tool for managing SR when planting SR-susceptible wheat varieties. In this work, we analyze the importance of detection and prevention of SR epidemics in Argentina under the described scenario and within the context of an integrated management of the disease.

Keywords: yellow rust, *Puccinia striiformis* f. sp. *tritici*, epidemiology, fungicides

INTRODUCTION

Importance of Wheat Stripe Rust

Wheat stripe rust (SR), caused by *Puccinia striiformis* Westend. f. sp. *tritici* Erikss (*Pst*), was first described by Gadd and Bjerkander in Europe in 1777 (Eriksson and Henning, 1896) and is widespread in all the wheat- growing regions of the world. Currently, SR is one of the most important and destructive diseases of wheat worldwide. The disease can cause up to 70% yield losses in highly susceptible wheat varieties (Chen and Kang, 2017a). Global yield losses were estimated at more than 5 million tons and annual economic losses at USD 1 billion (Beddow et al., 2015). Historically, wheat stem rust, caused by *Puccinia graminis* Pers. f. sp. *tritici* Eriks. & E. Henn. (*Pgt*), was considered the rust that caused the greatest losses in wheat crops (Beddow et al., 2015). However, in recent years, SR became the disease causing the greatest losses due to the recent epidemics registered around the world (Chen and Kang, 2017a). The SR causal agent, *Pst*, is an obligate biotrophic parasite that has a high variability and adaptability, continuously mutating into new races or pathotypes. This phenomenon is the main cause of the different wheat varieties genetic resistance breakdown by *Pst*. It is estimated that 88% of the world's wheat production is currently vulnerable to the pathogen (Beddow et al., 2015; Schwessinger, 2016). Because of all of the aforementioned characteristics, SR may be considered as the main phytosanitary challenge of wheat cultivation worldwide at present (Hovmøller et al., 2010, Chen et al., 2014, Beddow et al., 2015, Schwessinger, 2016).

The species of rust fungus *P. striiformis* is divided into several formae speciales (special forms) based on host specialization, i.e., varieties within this species (based on host specificity and/or morphological characteristics). It can infect different cereals such as wheat (*P. striiformis* f. sp. *tritici*), barley (*P. striiformis* f. sp. *hordei*), rye (*P. striiformis* f. sp. *secalis*), and different grasses such as *Agropyron* spp. (*P. striiformis* f. sp. *agropyri*) and *Elymus* spp. (*P. striiformis* f. sp. *elymi*) (Chen and Kang, 2017a; Huang et al., 2019). *Pst* is classified as a typical heteroecious, macrocyclic rust since the alternate hosts (*Berberis* spp. and *Mahonia* spp.) were recently identified (Jin et al., 2010; Wang and Chen, 2013). This discovery allows to ponder the impact of potential sexual recombination in generating new and more aggressive strains of the pathogen (Zhao et al., 2016; Mehmood et al., 2020a,b). For the case of Argentina, however, this aspect is unknown and there is no evidence to support that the sexual cycle of *Pst* actually occurs in nature in the Southern Cone of South America. Future research will be key in elucidating this unknown. The urediniospores (asexual spores of the pathogen) can be dispersed by wind over long distances and are responsible for severe epidemics that develop on wheat crops (Hovmøller et al., 2002). Therefore, it is believed that survival and initial inocula of wheat rusts occur on self-sown (voluntary) wheat plants in Argentina and neighbour countries at latitudes where frost does not occur during the off-season.

The SR epidemics that occurred in Argentina during the 2017/2018 growing season, coupled with the resulting yield losses, situate SR as one of the most economically important diseases of wheat in the country. This stems from the fact that wheat is the main cereal crop in the country, with a cultivated area of 6.7 million hectares and a total production of 18.5 million tons, per year (MINAGRI, 2018). This chapter describes how SR became the most

important disease in Argentina upon the incursion of new (exotic) pathogenic *Pst* races into the country. The chapter also addresses how detection and prevention of epidemics play a crucial role in SR integrated management.

Detection and Diagnosis of SR

In general, the geographic location and prevalence of rusts that attack cereals largely depend on the average temperature, the susceptibility of the wheat genotypes that are planted and the races of the pathogen present in each particular growing season. In Argentina, the three rusts that infect wheat are present. The most important is SR (Figures 1 to 6). The second in importance is leaf rust, caused by *Puccinia triticina* Eriks., which is common and endemic to South America (Figures 7 and 8) (Lindquist, 1982; Carmona et al., 2000, German et al., 2007). Finally, not less important is the stem rust, caused by *Pgt*, which can cause devastating epidemics in few days when infecting susceptible varieties (Figures 9 and 10) (Carmona et al., 2020). Leaf rust occurs more frequently than stem rust, but the prevalence and severity of the latter has increased in the last growing seasons in the Argentine Pampas region.

Wheat rusts are easy to distinguish between each other and from other wheat diseases, particularly when the pustules are young. The differences between the three rusts are summarized in Table 1. SR pustules are yellow orange arranged in stripes on leaves (Figure 1). When the disease becomes severe in susceptible varieties, SR can develop on glumes, lemma, palea and awns. The characteristic yellow color can be more easily distinguished during the morning because most spores are produced overnight (Stubbs, 1985; Chen, 2005). Generally, pustules are arranged in lines between leaf veins (Figure 2). However, sometimes uredinia do not appear in linear arrangement, especially in the seedling stage of some cultivars, and could cause the diagnosis to be difficult when trying to distinguish between SR from leaf rust (Figure 3). The same happens when the infection is very severe on the leaves of adult plants where the density of pustules does not allow to clearly distinguish the stripes (Figure 4) (Cheng, 2020). Dead stripes without pustules can often be observed on some leaves, especially after a late fungicide application or in varieties that show some type of resistance (Figure 5). Later, the teleutosoric pustules appear with black teleutospores that are also arranged in the form of stripes. These pustules tend to be more frequently arranged on the upper side of the leaves.

The interaction between the host plant (wheat), the pathogenic organism (causative agents of rusts) and the environment is visibly expressed through signs (pustules) and symptoms (chlorosis). These vary from its absence (immune wheat variety) to its maximum manifestation (susceptible cultivars). Symptoms and signs, therefore, are used to quantify these diseases. The number of pustules per leaf or the percentage of covered leaf area expresses the severity of the disease, while the percentage of plants or leaves attacked represents the incidence. The intensity of the disease is a function of the incidence and severity. The more susceptible the cultivar, the more virulent the rust races will be and if the environmental conditions are optimal for the development of the disease, then the maximum values of severity and incidence will be reached (Reis and Carmona, 2000).

In the particular case of SR, unlike other wheat rusts, at the beginning of the epidemics it is common to observe the symptoms and signs of the disease distributed in groups of few plants in the field, developing the typical infected patches known as “foci” or hot-spots (Figure 6). They can be seen in the distance as islands of yellowish spots or patches, up to 10 meters in diameter, in the middle of a wheat field. The foci pattern in hot spots would appear to be due to a combination of spore biology and morphology, moisture in the atmosphere and to greater susceptibility of upper leaves (Farber et al., 2017). If there is a high relative humidity, as it is frequent in winters of Argentina, most of the urediniospores are grouped together and remain in the air in small groups: they are relatively heavy and quickly fall out of the air, so their propagation takes place mainly over very short distances, generating so-called “hot spots” or foci. These hot-spots or patches can often be mistaken for nutrient deficiencies, waterlogging, or soil defects. Therefore, it is essential that when scouting, disease scouting be directed specifically at those spots. Because of the SR latent period (the time it takes for a spore to penetrate and infect until new pustules with urediniospores are produced), which usually takes between 10 to 14 days, it is very likely that after observing hot-spots, most plants in a whole field plot are infected. On the contrary, if there is not high relative humidity in the air, spores are dispersed in the air in an ungrouped manner and can travel considerably longer distances. This can give a uniform infection or generalized disease pattern development and not patches. SR spreads rapidly in the field and readily to other leaves and plants as infection of susceptible wheat varieties by *Pst* is highly effective. The proximity between wheat plants at normal planting densities (200-300 plants m²) facilitates natural infection and consequently increases the epidemic rate of development.

Table 1. Hosts and symptoms of leaf, stem and stripe rusts

Disease	Pathogen	Primary (uredinal/telial) hosts	Alternate (pycnial/aecial) hosts	Uredospores on primary host ⁽⁶⁾	Teliospores on primary host ⁽⁶⁾	Symptoms
Leaf rust	<i>Puccinia triticina</i> (Pt)	Common wheat (<i>Triticum aestivum</i> L.), durum wheat (<i>T. turgidum</i> L. var. <i>durum</i>), cultivated emmer wheat (<i>T. dicoccon</i>) and wild emmer wheat (<i>T. dicoccoides</i>), <i>Aegilops speltioides</i> , goatgrass (<i>Ae. cylindrica</i>), and triticale (X Triticosecale) ⁽¹⁾	<i>Thalictrum speciosissimum</i> (= <i>T. flavum glaucum</i>), <i>Isopyrum fumarioides</i> ⁽¹⁾	20-28 x 18-22 µm and have a diameter of 15 to 30 µm, subglobose and orange or reddish brown in color, with three to eight germinating pores distributed in their thick equimulate walls.	36-65 x 11-22 µm, bicellular, ellipsoidal, clavulate and pointed.	Typical leaf rust. Isolated or scattered uredinia on upper leaf surface.
Stem rust	<i>Puccinia graminis</i> f. sp. <i>tritici</i> (Pgt)	Common wheat (<i>Triticum aestivum</i> L.), durum wheat (<i>T. turgidum</i> L. var. <i>durum</i>), cultivated barleys (<i>Hordeum vulgare</i> L.), triticale (X Triticosecale) ⁽²⁾	Barberry (<i>Berberis</i> spp.), Oregon grape (<i>Mahonia</i> spp.), and their hybrids (× <i>Mahoberberis</i>) ⁽⁴⁾	17-25 x 18-22 µm, reddish orange, dehiscient and oblong oval.	39-57 X 15 X 18 µm, rounded and flattened at their apices, transversely septate into two cells, the lower one shortly pedicellate	Frequently on stem and spikes (glume and awns). Isolated uredinia on upper and lower leaf surfaces.
Stripe rust	<i>Puccinia striiformis</i> f. sp. <i>tritici</i> (Pst)	Common wheat (<i>Triticum aestivum</i> L.), durum wheat (<i>T. turgidum</i> var. <i>durum</i> L.), cultivated emmer wheat (<i>T. dicoccum</i> Schrank), wild emmer wheat (<i>T. dicoccoides</i> Kom), triticale (X Triticosecale), cultivated barleys (<i>Hordeum vulgare</i> L.), rye (<i>Secale cereale</i> L.), naturalized and improved pasture grass species (<i>Elymus canadensis</i> L., <i>Leymus secalinus</i> Hochst, <i>Agropyron</i> spp. Garetn, <i>Hordeum</i> spp. L., <i>Phalaris</i> spp. L., <i>Bromus unioloides</i> Kunth) ⁽³⁾	Barberry (<i>Berberis chinensis</i> , <i>B. koreana</i> , <i>B. holstii</i> , <i>B. vulgaris</i> , <i>B. shensiiana</i> , <i>B. potaninii</i> , <i>B. dolichobotrys</i> , <i>B. heteropoda</i> , etc.) and Oregon grape (<i>Mahonia aquifolium</i> , <i>Mahonia</i> spp., etc.) ^(3,5)	23-35 x 20-31 µm and have a diameter of 20 to 30 µm, yellowish orange, with thick walls equimulated with 6 to 12 germinative pores.	35-63 x 12-20 µm, subepidermal, frequently on sheaths, clavulate, with rounded apex, similar to those of <i>P. triticina</i>	Systemic uredinia on leaves (stripes) and spikes (glumes and awns)

Source: modified from Roelfs et al., 1992.⁽¹⁾ Bolton et al., 2008.⁽²⁾ Pgt was shown to infect 74 species in 34 genera in artificial inoculations of seedlings, but only 28 of those species belonging to eight genera were known to be natural hosts of the fungus (Leonard and Szabo, 2005).⁽³⁾ Chen et al., 2014.⁽⁴⁾ More than 90 species or varieties of *Berberis*, *Mahonia*, and their hybrids (× *Mahoberberis*) have been found to be susceptible to *P. graminis*; being *Berberis vulgaris* the most important species in North America and Europe (Roelfs, 1985).⁽⁵⁾ At present, 33 species of *Berberis* and *Mahonia* have been reported to be susceptible to *Pst* (Zhao et al., 2016).⁽⁶⁾ Indquist, 1982; Bushnell and Roelfs, 1984; Carmona et al., 2000.

The dispersal of urediniospores can be attributed to wind and rainsplash. Rains can favor the disease not because of its gravitational impact, but because they can guarantee humid hours to facilitate germination. However, excessive or intense rains could eliminate the spore stock in the air (Geagea et al., 1999). Urediniospores of SR can be spread by the wind from a few meters to more than 8000 km in the same growing season (Chen and Kang, 2017a; (Brown and Hovmøller, 2002). They have an adherent mucilaginous membrane and therefore can be dispersed mainly as groups of 2 to 10 spores (Rapilly et al., 1970). In contrast, spores of *Pgt* and *Pt* are mainly removed and dispersed as single spores (Geagea et al., 1997). According to Geagea et al. (1997), wind speed is very efficient at removing *Pst* urediniospores from diseased leaves at a speed of between 3 and 5 m s⁻¹. This dispersal ability causes fields to turn “yellow” in a few days, showing a large number of infected and sporulated wheat leaves. However, viable urediniospores are frequently dispersed within a certain region but may not be successful in initiating an epidemic. This is because wheat cultivars from that region may be resistant to the predominant genotype of the pathogen, environmental conditions after dissemination may be unfavorable or spores may arrive late with no time for the development of the epidemic.

Spore transport through human travel by aircraft can also contribute to the spread of the pathogen between countries. A clearly example was carried out by Wellings (2007) who demonstrated the introduction of *Pst* into Australia in 1979 from Europe, through contaminated passenger clothing.

Occurrence and Development Epidemics of SR in Argentina

According to available historical records, *Pst* was first reported in South America in the early 20th century, with an unknown origin (Rudorf and Job, 1934; Stubbs, 1985). Nevertheless, according to recent multilocus microsatellite genotyping studies, it is hypothesized that *Pst* migrated to South America from northwestern Europe in the early 1900s, probably through human intervention and not by wind (Ali et al., 2014). In Argentina, SR first appeared in 1929 attacking almost 80% of the total wheat grown area (Humphrey and Crowell, 1930). The following year the disease caused severe epidemics causing losses estimated at 2 million tons, representing 30% of the total production of that year (Fernández Valiela, 1979; Lindquist, 1982). At that time, Humphrey and Crowell (1930) suggested the possibility of SR being brought into the country from Europe in shipments containing wheat plant material with urediniospores. According to these authors, the disease was registered in an area of about 10 million hectares. The Tres Arroyos area located southeast of the province of Buenos Aires was one of the most attacked wheat regions at that time. In that location, there were two periods of disease attack: at the beginning of flowering (Zadocks 6.1 stage), by initial infections on lower leaves, and a more severe attack at the milky grain stage (Zadocks 7.5 stage). The spread of the epidemic was favored by the susceptibility of the varieties planted at that time (examples are Klein Record and Klein San Martín). High grain losses caused by SR forced growers to replace the most susceptible (and most planted) wheat varieties to the least susceptible (Fernández Valiela, 1979). Since 1930, the disease had only been sporadic and especially confined to regions with cooler temperatures in the southern wheat growing area of Buenos Aires province (German et al., 2007). Thus, Argentina was

historically considered marginally favorable for the epidemic development of SR due to its climate, except for the southern region of the Buenos Aires province with cooler average temperatures.

After almost 90 years of no epidemic occurrence, the agronomic scenario changed due to the introduction into the country of new races, virulent to the majority of Argentine wheat varieties. It was during the 2017/2018 and 2018/2019 growing seasons that SR was observed in regions with higher mean temperatures than those in south of the Buenos Aires province, where it had not been previously reported. The disease caused serious and widespread epidemics in many wheat growing regions of Argentina, specially in fields with high-water content soils and frequent dew formation. In total, more than 3 million hectares were affected including warmer areas of the Argentine Pampas for the first time. Unusual and early infections of SR were detected at several locations in the Entre Rios, Córdoba, Santa Fe, and Buenos Aires provinces. Typical “foci” or hot-spots were observed at the beginning of epidemics. The disease spread rapidly throughout most wheat-growing areas of the country and the SR was observed on almost all wheat cultivars (Carmona et al., 2019). During these two growing seasons, the Plant Pathology Department of the FAUBA coordinated a *Pst* survey in the Argentine Pampas region. During the first year of sampling, the SR foliar severity ranged from 5% to 50% depending on the particular crop environment and wheat variety. The maximum was registered in Pergamino, Buenos Aires (33°54'59.15"S; 60°27'30.92"W), and the minimum in Landeta, Santa Fe (31°59'00"S; 62°01'36"W). In the second year of sampling, SR foliar severity ranged from <1% in Alejo Ledesma (33°40'51.36"S, 62°37'49.48"W), Ordoñez (32°55'05.36"S, 62°53'59.71"W) and Oro Verde (31°51'24", 60°38'22"), to 80% in Famailá, Tucumán (27°03'14"S; 65°24'11"W). Likewise, samples of Triticale and Candeal wheat affected by SR were detected with a severity range of 1 to 5%.

Argentine *Pst* genetic lineages were analyzed by the Global Rust Reference Center (Aarhus University, Denmark). Annually, the GRRC elaborates a yellow rust genotyping and race analyses report based on a large number of samples being shipped from around the world. Genotyping was based on single sequence repeat (SSR) analysis and race phenotyping was based on bioassays of differential wheat lines using spore samples of recovered, pure isolates grown under strict experimental conditions (Hovmøller et al., 2019). A clear connection between the unusual epidemics and the incursion of new exotic SR strains into Argentina was evidenced. Genotyping results showed that a single genetic lineage named as *PstS13* was prevalent (80% of the sampled localities) in 2017 (Hovmøller et al., 2018). The testing of additional samples from 2018 confirmed the widespread of *PstS13* as it was completely dominating the composition of genetic lineages determined (100% of the sampled localities in Argentina) (Figure 11). Isolates of *PstS13* were first detected on Triticale giving rise to significant epidemics in Northern Europe in 2015. Later it was detected in Italy, Ukraine, Spain, Poland, Netherlands and three Scandinavian countries. Only a single race has been detected in the *PstS13* lineage in 2017 causing severe epidemics on bread wheat and durum wheat in Italy. Significant yield losses caused by highly aggressive *PstS13* isolates on multiple spring wheat (Carmona et al., 2019) and durum wheat (southern Europe) varieties and multiple triticale varieties (northern Europe and South America) were reported so far (Hovmøller et al., 2019). In 2019, a new *Yr10*-virulent variant in *PstS13* was detected in Europe. In Argentina, although only a single race (virulence phenotype: -,2,-,-,6,7,8,9,-,-,-

,-, -, -, -, AvS, -) has been detected irrespective of sampling origin, the determination of the particular race of *PstS13* is pending.

Figure 11a. Location of Argentinean wheat fields in South America sampled for SR epidemic monitoring.

Figure 11b. (Continued).

Figure 11b. Location of wheat fields sampled in 2017 (squares) and 2018 (black dots) in Argentina for SR epidemic monitoring.

A different genetic lineage, *PstS14*, first detected in Europe in 2016 and Morocco, Africa in 2017, was also detected in Argentina in 2017 epidemics with a prevalence of 13% (Hovmøller et al., 2018). Further, another genetic lineage harboring the ‘Warrior’ race, *PstS7*, was detected in only one sample (2.6% prevalence) in Argentina in 2017. The first confirmation of the detection of this lineage in Argentina in a non-epidemic situation was in 2015. The *PstS7* isolates from Argentina (both 2015 and 2017) were unique, diverging by 1-2 alleles from the *PstS7* isolates in Europe and West Asia (Hovmøller et al., 2018). These findings are in agreement with the hypothesis proposed by Ali et al. (2014) that Europe could be the source of origin of the SR populations infecting wheat in South America. Isolates of the *PstS13* lineage were detected in 2017 both in Italy and Argentina causing severe epidemics on wheat. The about 12,000 km separation distance between these geographic regions suggests a high global dispersal capacity of *Pst*. However, this hypothesis has yet to

be demonstrated at least with dispersion prediction models according to the prevailing global circulation patterns.

An important component in the onset and development of rust epidemics is the role of alternate hosts of *Pst*. To date, however, for the case of SR there is no evidence or relationship that secondary hosts may play a key roll in the epidemiology of the disease in Argentina (Carmona et al., 2020), even though SR has been detected in triticale (X Triticosecale), rye (*Secale cereale*) and tricepiro (hexaploid Triticale x octoploid Trigopyre).

Although the information available is not sufficient to fully clarify the epidemiology of the disease in Argentina, we hypothesize that: (i) the recent widespread SR epidemics caused by new aggressive *Pst* strains in Argentina were the result of direct introductions of airborne urediniospores from inoculum source areas in southern Africa, and (ii) the spatio-temporal progress of disease in the wheat growing regions of the country was the result of intermittent spore reintroductions in air parcels or land bridge inoculum accumulation in host areas resulted from short-distance dispersal of spores by surface winds. Research exploring these areas is underway. This analysis paves the way to new studies on control and understanding of the biology of this pathogen.

Preventing SR Epidemics

Wheat SR epidemiology has changed dramatically in Argentina since 2017 in terms of cultivar susceptibility and disease severity. Unlike other regions of the world where SR occurrence has increased during the last 20 years, recent SR epidemics in Argentina were built up over three years and have been the most severe since 1930. It is expected that SR epidemics will continue to occur due to the presence of new SR strains virulent on wheat varieties and because most of the high yield potential wheat cultivars that are planted in the country are highly susceptible to SR. For all this, the risks of SR epidemics and susceptibility response of wheat cultivars to the pathogen strains has become unpredictable for wheat producers and plant breeders.

Integrated management of SR should combine control strategies such as planting SR-resistant wheat varieties, development of local or regional infection risk models to predict SR epidemics, frequent scouting, balanced fertilization, appropriate use of efficacious fungicides (seed and foliar treatment) and development of local or regional decision support tools for timing fungicide applications. It is likely that SR-resistant wheat varieties with appropriate level of durable resistance be developed in the near future. Planting of such varieties should be promoted or encouraged to avoid planting a few varieties with high-yield potential but highly SR-susceptible in the largest proportion of the wheat area. Additionally, it is highly recommended to scout not only SR-susceptible cultivars but also SR-resistant varieties that can be broken down within a few years after their release. Some cultural practices can contribute to the increase of an epidemic if they contribute to create a greater number of infected volunteer plants, vegetating during the period between wheat crops.

The use of fungicides has become one of the most important tools for SR control worldwide, especially when susceptible genotypes are planted. Numerous fungicides formulations are available for SR control in the different wheat growing regions of the world (Carmona et al., 2020). The combination choice of fungicide active ingredients (a.i.), time

and rate of application must be defined for each field depending on the level of genetic resistance to SR of the planted wheat variety, the level of disease intensity and the forecast of weather variables conducive to disease development. One of the most important points is the optimal timing for fungicide application according to scientific criteria. Late fungicide applications are ineffective and have a reduced yield economic response. We proposed the development of a local or regional economic damage threshold (EDT). For example, 10–20% of SR foliar incidence from the Z3.0 wheat growth stage is a preliminary guideline in Argentina (Carmona et al., 2019). Following this recommendation, several field trials with fungicides were carried out. During the 2017/2018 growing season, trials were conducted in Landeta, Santa Fe province, with yield responses to fungicide as high as 3091 kg ha⁻¹ and 4743 kg ha⁻¹ for one and two sprays in susceptible wheat genotypes, respectively. The results indicated that one or two fungicide applications significantly decreased SR intensity and increased the wheat grain yield. In 2019, a field trial was conducted in Bigand, Santa Fe (-35.5963 S, -62.9838 W), in order to determine the effect of different fungicide a.i. efficiency on SR control and its impact on wheat grain yield. Significant differences occurred between treated and untreated plots. One application of Allegro® (kresoxim-methyl 12.5% + epoxiconazole 12.5%) at Z3.1 resulted in 1,323 kg ha⁻¹ yield increase. Treatments with two fungicide applications of Allegro® (kresoxim-methyl 12.5% + epoxiconazole 12.5%) + Opera® (pyraclostrobin 13.3% + epoxiconazole 5%) in Z3.1 and Allegro® (kresoxim-methyl 12.5% + epoxiconazole 12.5%) + Orquesta Ultra® (fluxapiroxad 5% + pyraclostrobin 8.1% + epoxiconazole 5%) in Z3.9 controlled > 90% of the SR severity, with a significant yield increase of 2373 and 2217 kg ha⁻¹, respectively, compared to the untreated control. These data confirm the potentially damaging effects of SR in susceptible wheat varieties in Argentina and the high efficacy of different fungicidal active ingredients for its control. Carmona et al. (2020) recently published a comprehensive review of the impact and role of fungicides in the integrated management of SR. This review further summarizes the registered fungicides and timing of foliar spray that are recommended worldwide.

CONCLUSION

Despite the potential damage that SR can cause in wheat crops in Argentina and elsewhere, and the relatively low cost of fungicides to control the disease effectively, it is likely that Argentina growers will continue to plant high-yield potential, yet highly SR susceptible wheat varieties. Our analysis suggests that to achieve an efficient and complementary management of SR, regional disease early warning system and government programs should be implemented. Efforts must include early monitoring in the growing season, starting in the fields with the highest epidemiological risk, using sentinel plots and weather monitoring. It is emphasized that the quantitative monitoring and image processing of urediniospores efficiently captured from wheat fields could provide critical information for SR prediction (Lei et al., 2018). Further, the need for SR scouting and monitoring for emergence of fungicide resistance are key points to assist growers.

In this review, we have outlined a detailed description of the morphological characteristics that must be recognized for an early diagnosis of SR. Diagnosis should couple visual disease monitoring in wheat crops as well as in volunteer wheat plants where inoculum

could cause primary infections early in the growing season. Our extensive work on chemical control of SR and assessments of economic losses indicate that timing detection of SR and weather monitoring are paramount for fungicide application decisions, which are conducive to prevention of disease or reduction of the amount of initial inoculum.

Chapter 380

GLYCOENGINEERING OF VACCINES THAT HARNESSING THE NATURAL ANTI-GAL ANTIBODY INCREASES IMMUNE PROTECTION IN VIRAL EPIDEMICS

Uri Galili*

Department of Medicine, Rush University School of Medicine,
Chicago, Illinois, USA

ABSTRACT

The main protective mechanism in humans against viral epidemics is the activity of the immune system which produces neutralizing antibodies that prevent the virus from infecting cells and destroy it. The immune system also produces T lymphocytes that kill cells infected by the virus and thus prevent further replication of the virus. In each infected individual there is a “race” between the replicating virus damaging various tissues and the immune system preventing infecting viruses from reaching a lethal mass. In some epidemics or pandemics, the immune system of many individuals fails to “catch up” with the expanding virus populations, resulting in death of the infected person. The development of vaccines prepared of inactivated virus, attenuated virus, or of isolated viral proteins (subunit vaccines) has enabled the “education” of the immune system to fight effectively the infectious virus by inducing expansion of lymphocyte populations that react rapidly against the antigens of the virus. Thus, upon infection, these expanded virus specific lymphocyte populations are activated to neutralize and destroy the virus thereby stopping its replication and preventing its deleterious effects. However, some vaccines are suboptimal and do not elicit a sufficiently protective immune response in many of the vaccinated individuals (in particular in elderly populations). In a number of viral vaccines the low immunogenicity (i.e., efficacy) is caused by the masking (i.e., camouflaging) of vaccinating viral antigens by multiple carbohydrate chains (glycans) forming “glycan shields” that are not recognized by the immune system as foreign antigens (e.g., HIV and SARS-CoV-2 causing the COVID-19 pandemic).

* Corresponding Author’s Email: uri.galili@rcn.com.

Immunogenicity of such viral vaccines may be markedly amplified by a novel immunotherapeutic approach which harnesses a natural antibody that is produced in large amounts in all humans who are not severely immunosuppressed. This antibody is called the “natural anti-Gal antibody” and the carbohydrate antigen it binds is the “ α -gal epitope” with the structure Gal α 1-3Gal β 1-4GlcNAc-R. This chapter describes amplification of anti-viral vaccines immunogenicity by modifying the glycans on the glycan shield of the virus, referred to as “glycoengineering.” Such amplification of vaccine immunogenicity is achieved by glycoengineering the vaccinating inactivated virus or its subunit vaccine to present α -gal epitopes. Upon vaccination with these vaccines (called “ α -gal vaccines”), the natural anti-Gal antibody binds to the multiple α -gal epitopes presented on the α -gal vaccine and forms immune complexes with it. The Fc portion of anti-Gal in these immune complexes binds to Fc receptors on antigen presenting cells (APC) and induces extensive uptake of the vaccine by APC, mediated by active endocytosis. In the absence of immune complexes, the uptake is suboptimal due to random pinocytosis. The ensuing extensive transport of these immune complexes to regional lymph nodes by the APC results in 10-200 fold higher antibody and T cell immune response than with vaccines that are not immunocomplexed. This is shown in this chapter with influenza inactivated whole virus and with gp120 envelope glycoprotein of HIV vaccines. Studies in anti-Gal producing mouse experimental model demonstrated a much higher survival of animals immunized with influenza α -gal vaccine and challenged with a lethal dose of the virus, than following immunization with vaccine presenting unmodified glycan shield. This chapter further describes a number of methods for glycoengineering of COVID-19 virus to present multiple α -gal epitopes for amplification of α -gal vaccine efficacy against SARS-CoV-2 infections.

INTRODUCTION

The key prophylactic protective method against infection by epidemic causing viruses which are transmitted from mammalian reservoirs (zoonotic virus) or from infected humans is immunization with a vaccine that elicits an immune response against the virus. Such a protective immune response is mediated by antibodies that neutralize and destroy the virus thus preventing the virus from penetrating into host cells. This protective immune response also includes T cells that identify and kill virus infected cells, thereby preventing further infection of cells and replication of the virus. Viruses causing epidemics usually display poor immunogenicity, i.e., the ability of the immune system to mount a rapid protective immune response is limited. This is because the immune system fails to recognize fast enough the virus as an invading microbial agent that should be destroyed. In each infected individual there is a “race” between the replicating virus damaging various tissues and the immune system preventing infecting viruses from reaching a lethal mass. In lethal epidemics, the immune system of many individuals fails to “catch up” with the expanding virus population, resulting in death of the infected person. Vaccination of populations in danger of being infected by the harmful virus introduces into the vaccinated individual harmless viral proteins (or genes coding for these proteins), thus “fooling” the immune system to sense a viral attack. This enables the “education” of the immune system to fight effectively the infectious virus by

inducing expansion of the lymphocyte populations that react rapidly and specifically against the proteins of the virus (i.e., viral antigens). Thus, upon infection by the lethal virus during an epidemic, the expanded populations of virus specific lymphocytes are rapidly activated to produce antibodies that neutralize (i.e., prevent the virus from attaching to cells and infecting them) and destroy the virus by activation of the complement system to forms “holes” in the envelope of the virus. In addition, virus specific T lymphocytes kill cells infected by the virus, thereby stopping its replication and expansion and preventing further viral deleterious effects.

Some vaccines are not effective enough in eliciting a protective immune response in a significant proportion of the vaccinated individuals (in particular in elderly populations). Among the reasons for this suboptimal efficacy are:

- 1) *Seasonal epidemics* – Changes in viral antigens in some seasonal epidemics (e.g., influenza) which prevent recognition of the infectious virus by the immune system of individuals immunized with vaccines prepared from a previous season virus.
- 2) *Low immune response to new antigens in the elderly*- Some vaccines are less effective in the elderly in eliciting long lasting anti-viral protective immune response than in young populations, as demonstrated with influenza vaccines (Webster, 2000; Katz et al., 2004; Chang et al., 2012). Because of these differences, mortality among the elderly infected during the seasonal outbreak of influenza virus is much higher than among young patients. Moreover, the lower immune response to SARS-CoV-2 infection makes the elderly much more susceptible to the detrimental effects of the virus, as indicated by the much higher mortality rate of COVID-19 among elderly than in young individuals (CDC, 2020; Liu et al., 2020). Among the many reasons for the significantly lower immune response in the elderly are the near complete to complete elimination of the thymus (main site for T cell differentiation) in individuals 65 year old or older (Kendal et al. 1980), telomere erosion in lymphocytes, damaged DNA and mitochondrial disfunction (Akwbar & Gilroy 2020). A common clinical example which demonstrates the differences between the potent immune response in young vs. lesser immune response in the elderly is the replacement of impaired heart valves with porcine heart valve in the two age groups. Because of the extensive immune response against the porcine antigens in young recipients, the porcine heart valve function is impaired in 100% of <35 year old young recipients within <5 years. Therefore, young patients are implanted with mechanical heart valve that requires constant anticoagulation therapy (Wang et al. 2017). In contrast, the very weak immune response against the porcine implant antigens in elderly recipients (>70 year old) enables appropriate function of porcine heart valve implants for 10-20 years.
- 3) *Glycan shields on viruses* – Enveloped viruses usually have carbohydrate chains (glycans) linked to their envelope proteins. In a large proportion of these viruses, the multiple glycans “camouflage” the virus by forming a “glycan shield” that “hides” immunogenic peptides of envelope glycoproteins (Walls et al. 2016; Yang et al. 2020; Watanabe et al. 2020). This camouflaging results in low immunogenicity of vaccines made of such viruses, or of their envelope glycoproteins, leading to low efficacy of the protective immune response elicited by the vaccine. Suboptimal efficacy of viral vaccines was attributed to the glycan shield masking antigens in vaccines of enveloped viruses such as hepatitis C virus vaccine (Ahlén & Frelin

2016), HIV vaccine (Goulder & Watkins 2004; Lewis et al. 2014) and influenza virus vaccine (Wei et al. 2003; Chang et al. 2012; Wei et al. 2010).

All these shortcomings of some viral vaccines raise the need for developing methods that increase immunogenicity and efficacy of vaccines. This chapter describes a method for achieving this objective by altering (called here glycoengineering) the structure of the glycan shield on enveloped virus vaccines, thereby harnessing the immunologic potential of an abundant antibody in humans, called the natural anti-Gal antibody which constitutes ~1% of circulating immunoglobulins. Experimental studies in mice with vaccines described in this chapter, were found to increase immunogenicity of viral vaccines by 10-200 fold. Thus, it is suggested that the proposed glycoengineering may also markedly increase the efficacy of vaccines protecting humans against viral epidemics.

Viral vaccines are usually of three kinds: 1. Vaccines prepared from the inactivated (killed) virus (called inactivated whole virus vaccine), from its proteins (split or subunit vaccine) or from recombinant viral proteins produced in eukaryote or prokaryote expression systems. 2. Gene based vaccines made of gene(s) of viral proteins that are injected into tissues (usually muscles) of the vaccinated individuals for production of the vaccinating protein by the individual's own cells. 3. Attenuated virus vaccines which consists of virus that does not cause the disease but has proteins that immunize the vaccinated individual against the epidemic causing virus. This chapter discusses methods for increasing the efficacy of vaccines included in the first group above and which are prepared against enveloped viruses. The glycoengineering of the vaccine aims to manipulate the glycans on the envelope glycoproteins to present a carbohydrate antigen called the " α -gal epitope," which is the antigen binding the natural anti-Gal antibody. This epitope is illustrated on the right glycan in Figure 1.

Following the injection of virus vaccines (e.g., influenza virus vaccine) into the arm muscle, nothing happens at the injection site other than internalization of the vaccinating envelope proteins or of the inactivated whole virus by antigen presenting cells (APC), such dendritic cells and macrophages. This uptake of the vaccine is mediated by random internalization of small droplets (pinocytosis) of the suspension of vaccinating proteins or inactivate virus that are in the vicinity of the APC. This uptake is nonspecific and the efficacy of internalizing vaccines into APC is moderate. The vaccinating proteins are transported by APC to regional lymph nodes. The APC further process the vaccinating proteins into small peptides which are presented on MHC molecules. These presented peptides interact with the corresponding T cell receptors (TCR) and activate the peptide specific CD4⁺ and CD8⁺ T cells (Banchereau & Steinman, 1998; Zinkernagel et al. 1997). The activated CD8⁺ T cells proliferate, then leave the lymph nodes, circulate in the body, detect and kill cells containing replicating virus. Activated CD4⁺ T cells proliferate and function as helper T cells which help B cells to produce antibodies against the infecting virus, as well as secrete cytokines helping proliferation of CD8⁺ T cells and their maturation into cytotoxic T cells (CTL) that kill host cells infected by the virus.

Figure 1. Structure of N-linked glycans on viral envelope glycoproteins and synthesis of α -gal epitopes on these glycans. Left glycan- Carbohydrate chains of the complex type are synthesized on asparagine (N) in the sequon N-X-S/T (asparagine-any amino acid-serine or threonine). Many of these glycans are capped by sialic acid (SA). Center glycan- Sialic acid capping the glycan is removed by neuraminidase to expose the penultimate Gal $\beta 1$ -4GlcNAc-R (N-acetylglucosamine- LacNAc). In glycans of influenza virus the SA is absent because it is eliminated by the viral neuraminidase. Right glycan- Incubation of inactivated virus or soluble envelope glycoproteins carrying the desialylated glycans, with recombinant (r) $\alpha 1,3GT$ and with the sugar donor uridine diphosphate galactose (UDP-Gal), in the presence of Mn^{++} , results in synthesis of α -gal epitopes (Gal $\alpha 1$ -3Gal $\beta 1$ -(3)4GlcNAc-R) on the glycan. These epitopes readily bind the natural anti-Gal antibody, thereby forming immune complexes with viral vaccines presenting α -gal epitopes. From Galili U. *The natural anti-Gal antibody as foe turned friend in medicine*. Academic Press/Elsevier, Publishers, London (2018), page 152.

One of the critical factors in the process inducing a protective anti-viral immune response by vaccination is the extent of vaccine uptake by the APC. As indicated above, one reason for the suboptimal uptake of vaccines by APC is the random pinocytosis which occurs in many cells and results in internalization of vaccinating virus or proteins that accidentally are near the cell membrane. Another reason for suboptimal uptake by APC is the negative charges on viral vaccines. Enveloped virus vaccines usually present multiple sialic acid residues on their glycan shield (with the exception of influenza virus). Examples for such envelope glycoproteins are the spike (S) protein of the SARS-CoV-2 virus causing the COVID-19 pandemic and gp120 of HIV. The sialic acid has a negative electrostatic charge. When approaching the cell membrane of APC, negative charges on the vaccinating virus or viral glycoproteins and those on the cell surface of APC create electrostatic repulsion (zeta (ζ) potential) that deflects the virus or viral glycoprotein and thus decreases uptake of vaccines (Galili, 2018). Increased uptake of vaccines, which results in increased vaccine immunogenicity, can be achieved by formation of immune complexes between the vaccine and the corresponding IgG antibody. The high affinity interaction between the Fc portion of the immunocomplexed IgG molecule and Fc γ receptors (Fc γ R) on the cell membrane of dendritic cells and macrophages results in effective targeting of the immunocomplexed vaccine to APC. Binding of the Fc portion of the immunocomplexed antibody to Fc γ R on the APC generates a signal that stimulates APC to internalize the immunocomplexed vaccine by active endocytosis (Clynes et al. 1998; Schuurhuis et al., 2002; Regnault et al., 1999). The

result of this extensive endocytosis is a marked increase in uptake, processing and presentation of vaccine peptides by APC that leads to increased immunogenicity of the vaccine, thus amplifying its efficacy.

Figure 2. Anti-Gal mediated targeting of vaccinating viral envelope glycoproteins to APC. (A) The negative charges of sialic acid (SA) on the glycan shield of viruses and on the APC surface glycans generate electrostatic repulsion (ζ (zeta)-potential) between the inactivated virus or the virus glycoproteins vaccines and the APC. This electrostatic repulsion decreases the uptake of vaccines by random pinocytosis into the APC. (B) Glycoengineering of the viral glycan shield by replacing SA with α -gal epitopes, eliminates the electrostatic repulsion and enables binding of the natural anti-Gal IgG antibody to the glycoprotein and formation of immune complexes. The binding of the Fc portion of anti-Gal in the immune complexes to Fc γ receptors (Fc γ R) on APC induces extensive uptake of the vaccine by endocytosis into APC thus greatly increasing immunogenicity of vaccines. Modified from Galili U. *The natural anti-Gal antibody as foe turned friend in medicine*. Academic Press/Elsevier, Publishers, London (2018), page 160.

Amplification of the immune response following vaccination with immunocomplexed vaccines in comparison to vaccines delivered without an immunocomplexed antibody has been known for ~60 years. Among the vaccines shown to increase the immune response when immunocomplexed with their corresponding antibodies were tetanus toxoid (Stoner and Terres, 1963; Manca et al. 1991; Gosselin et al. 1992; Fanger et al. 1996), hepatitis B envelope antigen (Celis and Chang, 1984), Venezuelan equine encephalitis virus (Houston et al. 1977), simian immunodeficiency virus (SIV) (Villinger et al., 2003) and *Trypanosoma* (Stäger et al. 2003). The immune response against these vaccines immunocomplexed with the corresponding antibody was reported to be 10-1000-fold higher than with the same vaccine in the absence of immunocomplexing antibody. With the understanding of APC role as cells internalizing vaccines, transporting the internalized vaccines to regional lymph nodes, processing them and presenting the immunogenic peptides to T cells with the corresponding

TCR, it became evident that the Fc portion of the antibody immunocomplexed to vaccines targets the vaccine for effective binding to Fc receptors of APC, induction of extensive endocytosis into APC and maturation of these cells to professional APC (Clynes et al. 1998; Regnault et al. 1999; Schuurhuis et al. 2002).

The use of vaccines immunocomplexed with their specific antibodies has not resulted in their extensive use in the clinic for several reasons: 1. The antibodies for each of these vaccines have to be purified and complexed *in vitro* with the vaccine. Preparation of standardized immune complexes and the preservation of such immune complexes without inactivation of the antibody are difficult. 2. The immunocomplexing antibodies may be available from non-human species (including monoclonal antibodies) which may elicit an anti-antibody immune response in vaccinated individuals. 3. The immunocomplexed antibodies may mask immunodominant peptide epitopes on the vaccinating antigen within the immune complexes, thereby decreasing the efficacy of the vaccine. The present chapter describes a method for targeting immunocomplexed enveloped virus vaccines and avoiding the difficulties listed above by harnessing the natural anti-Gal antibody. Immune complexes are formed at the vaccination site between the endogenous natural anti-Gal antibody of the vaccinated individual and viral vaccines glycoengineered to present the carbohydrate antigen binding anti-Gal, i.e., the α -gal epitope (right glycan in Figure 1). This chapter describes an experimental model that demonstrates the mechanism and efficacy of this method and the marked increase in the immunogenicity of influenza virus and gp120 of HIV vaccines glycoengineered to present α -gal epitopes. Such vaccines are referred to as “ α -gal vaccines.” Since this chapter is written ~10 months into the COVID-19 pandemic, the chapter further describes possible preparation of future α -gal COVID-19 vaccines that harness the natural anti-Gal antibody for the formation of immune complexes targeted to APC.

The method for enhancing immunogenicity of vaccines by glycoengineering them to present α -gal epitopes was originally used for conversion of tumors into vaccines that amplify the immunogenicity of autologous tumor antigens (Galili & LaTemple, 1997; LaTemple et al. 1999; Rossi et al. 2005; Galili et al. 2007; Abdel-Motal et al. 2009a). This chapter demonstrates the use of the same principle in amplifying viral vaccine immunogenicity. Viral α -gal vaccines have not been studied yet in humans. Thus, this chapter includes several figures associated with the studies of α -gal viral vaccines in murine experimental models. The presented results strongly suggest that a similar increased efficacy may be feasible with human viral vaccines glycoengineered to present multiple α -gal epitopes.

THE NATURAL ANTI-GAL ANTIBODY SIGNIFICANCE IN AMPLIFYING α -GAL VACCINE IMMUNOGENICITY

The Natural Anti-Gal Antibody and the α -Gal Epitope

The human immune system constantly produces natural antibodies without active vaccination. The antigens (ligands) of many of the natural antibodies in humans are various carbohydrate antigens (Blixt et al. 2004; Bovin, 2013; Stowell et al. 2014). Many of these antibodies are produced in response to antigenic stimulation by carbohydrate antigens on bacteria of the natural gastrointestinal (GI) flora (Wiener, 1951; Springer, 1971; Hooper &

Macpherson, 2010). Fortuitously, a number of these antibodies, although produced against bacterial carbohydrate antigens, also bind to mammalian carbohydrate antigens produced in species other than humans. These antibodies function as an important immune barrier against zoonotic viruses carrying carbohydrate antigens produce in various mammalian hosts (Galili 2020a). One of the major natural anti-carbohydrate antibodies in humans is the natural anti-Gal antibody (also known as anti- α -galactosyl and anti-Gal α 1-3Gal). Anti-Gal is abundant in human, constituting ~1% of serum IgG, IgM, and IgA immunoglobulins (Galili et al. 1984, Galili, 2013; Hamadeh et al. 1995; McMorro et al. 1997; Parker et al. 1999). Anti-Gal is also found as IgA and IgG antibodies in a variety of body secretions including milk, colostrum, saliva, and bile (Hamadeh et al. 1995). Anti-Gal is found in the blood of individuals of all ages (Wang, 1995) and is produced as the result of continuous antigenic stimulation by carbohydrate antigens on GI bacteria such as *Serratia*, *Klebsiella* and *E. coli* (Galili et al. 1988a; Mañez et al. 2001; Posekany et al. 2002). When human circulating B cells are stimulated to produce antibodies, as many as 1% of these cells produce anti-Gal (Galili et al. 1993). Anti-Gal is a polyclonal antibody (Galili et al. 1984). In blood-group A and O individuals, anti-Gal also comprises >80% of the anti-blood-group B activity (Galili et al. 1987a).

Anti-Gal binds specifically to a carbohydrate antigen called the α -gal epitope, with the structure Gal α 1-3Gal β 1-(3)4GlcNAc-R on glycans linked to mammalian glycoproteins, glycolipids, and proteoglycans (Galili et al. 1985; 1987b; Towbin et al. 1987; Teneberg et al. 1996) (Figures 1 and 2B). The α -gal epitope is abundantly found on cells and on secreted glycoproteins of all mammals that are not monkeys or apes (non-primate mammals including both marsupials and placentals), in lemurs (prosimians that evolved in Madagascar), and in monkeys of South America (New World monkeys) (Table 1) (Galili et al. 1987b, 1988b). In all these mammals the α -gal epitope is synthesized by a glycosylation enzyme called α 1,3galactosyltransferase (α 1,3GT), which catalyzes the synthesis of α -gal epitopes by the second enzymatic the reaction illustrated in Figure 1 (Basu & Basu, 1973; Blake & Goldstein, 1981; Blanken & Van den Eijnden, 1985; Galili et al. 1988b). The α -gal epitope is absent in vertebrates which are not mammals, including birds, reptiles, amphibians and fish, implying that this enzyme appeared early in mammalian evolution before marsupials and placentals diverged from a common ancestor (Galili, 1988b). In contrast to New World monkeys, lemurs and non-primate mammals, the Old World monkeys (monkeys of Asia and Africa), apes, and humans completely lack α -gal epitopes because of inactivation of the α 1,3galactosyltransferase gene (also called α 1,3GT gene, or *GGTA1*) in ancestral Old World primates 20-30 million years ago (Galili et al. 1987b, 1988b; Larsen et al. 1990; Galili & Swanson, 1991; Koike et al. 2002; Lanterni et al. 2002). Instead, humans, apes and Old World monkeys, all produce the natural anti-Gal antibody in large amounts (Table 1) (Galili et al. 1984; 1987b; Teranishi et al. 2002). Because of this distribution of anti-Gal and the α -gal epitope, transplantation of porcine xenografts into Old World monkeys or humans results in rapid (hyperacute) anti-Gal mediated rejection of the graft (Galili, 1993; Good et al. 1992; Cooper et al. 1993; Sandrin et al. 1993). As discussed below, a plausible cause for the evolutionary elimination of the α -gal epitope in ancestral Old World primates could be a virus mediated pandemic which eliminated α -gal epitopes synthesizing primates and survival of few progeny in which the α 1,3GT gene was accidentally inactivated, resulting in production of protective natural anti-Gal antibody.

Table 1. Reciprocal distribution of the natural anti-Gal antibody (Ab) and its ligand the α -gal epitope in mammals

Animal group	α 1,3galactosyl-transferase	α -gal epitope (Gal α 1-3Gal β 1-4GlcNAc-R)	Natural anti-Gal Ab
Nonprimate mammals	+	+	-
Prosimians (lemurs)	+	+	-
New World monkeys	+	+	-
Old World monkeys	-	-	+
Apes	-	-	+
Humans	-	-	+

Evolutionary Causes for the Appearance of the Natural Anti-Gal Antibody

Mammals synthesizing α -gal epitopes are immunotolerant to this carbohydrate antigens which is a self-antigen in them and thus, do not produce the natural anti-Gal antibody. Since New World monkeys and nonprimate mammals synthesize the α -gal epitope, it is probable that ancestral Old World primates also synthesized this antigen. The complete lack of α 1,3GT activity in Old World monkeys, apes and humans (Table 1) implies that the α 1,3GT gene was inactivated and thus the α -gal epitope was eliminated in ancestral Old World primates after they were geographically separated from New World monkeys. A plausible scenario for this evolutionary event is the elimination of Old World primates synthesizing the α -gal epitope in the course of an epidemic occurring in the Africa-Eurasia land mass, mediated by a virus that was lethal to primates. However, few primate progeny in which the α 1,3GT gene (*GGTA1*) was accidentally inactivated by one or few base deletion mutations, survived this putative epidemic. In the absence of α -gal epitopes, these progeny lost the immune tolerance to the α -gal epitope and produced the natural anti-Gal antibody due to antigenic stimulation by GI bacteria. Synthesis of glycans on viral glycoproteins is mediated by the host cell glycosylation machinery. Therefore, virus replicating in the ancestral primates synthesizing α -gal epitopes and killing them also presented this epitope on its envelope glycoproteins. This resulted in neutralization and destruction of such viruses by anti-Gal following infection of progeny lacking α -gal epitopes and producing this antibody. Ultimately, this evolutionary process resulted in complete replacement of α -gal epitope producing Old World primates with primates lacking this epitope and producing the natural anti-Gal antibody (Galili, 2019). New World monkeys evolving in the continent of South America and lemurs evolving in the island of Madagascar were not subjected to this selective process because of the oceanic barriers between them and the primates in Eurasia-Africa. Anti-Gal was also found to bind and kill some protozoa such as *Plasmodium* (Yilmaz et al. 2014), *Trypanosoma* (Portillo et al. 2019) and *Leishmania* (Iniguez et al. 2017). Thus, such pathogens may also be considered as a theoretical cause for the elimination of ancestral Old World primates synthesizing the α -gal epitope and survival of the few progeny producing natural anti-Gal antibody. However, the complete elimination of primates synthesizing α -gal epitopes in all geographic and climate zones of Eurasia-Africa suggests that a virus with very high capacity of spreading throughout populations, is a more likely candidate for a pathogen mediating this selection process this land mass.

Hypothesis on Anti-Gal Mediated Amplification of Viral Vaccine Immunogenicity

The observations above on increased immunogenicity of vaccines administered as immune complexes with their corresponding antibodies suggest that amplification of vaccine immunogenicity may be achieved by formation of immune complexes also with the natural anti-Gal antibody, provided that the vaccines include glycoproteins that carry multiple α -gal epitopes on their glycans. Such an α -gal vaccine in the form of inactivated whole virus may be used as an example. It could be hypothesized that immunization with inactivated virus glycoengineered to present α -gal epitopes will result in the formation of immune complexes between anti-Gal and the α -gal vaccine at the vaccination site. The immunization process by α -gal vaccines is hypothesized to occur in several steps which are illustrated below in Figure 3.

Figure 3. Suggested mechanism for amplification of α -gal vaccine immunogenicity by anti-Gal mediated targeting to APC. Inactivated whole virus vaccine presenting multiple α -gal epitopes is used as a vaccine example. Step 1- The injected virus vaccine forms immune complexes with anti-Gal IgM and IgG molecules thereby activating the complement system to generated complement cleavage peptides C5a and C3a. These chemotactic peptides recruit dendritic cells and macrophages that function as APC. Step 2- Anti-Gal IgG coating the virus targets it for extensive uptake by the recruited APC, mediated by Fc/Fc γ receptors (Fc γ R) interaction between the immunocomplexed vaccine and the APC. Step 3- APC transport the internalized virus vaccine to the regional lymph nodes and process the virus antigens. Within the lymph nodes, APC present the immunogenic viral peptides on MHC molecules. These peptides engage CD4⁺ and CD8⁺ T cells with the corresponding TCR and activate these lymphocytes which proliferate and leave the lymph nodes. TCR- T cell receptor. Modified from “*The natural anti-Gal antibody as foe turned friend in medicine*” by U. Galili, 2018, Elsevier/Academic Press, p. 153.

Step 1

Formation of immune complexes between anti-Gal IgM and IgG molecules and the α -gal vaccine will activate the complement system and generate chemotactic complement cleavage peptides such as C5a and C3a which recruit APC, including macrophages and dendritic cells, to the vaccination site.

Step 2

Anti-Gal IgG molecules bound to α -gal epitopes of the vaccinating virus glycoproteins will target the vaccine for extensive uptake by the recruited APC as a result of the interaction between the Fc portion of anti-Gal IgG molecules bound to α -gal epitopes on the vaccinating virus and Fc γ receptors (Fc γ R) of the recruited APC. This interaction generates a signal that induces active and extensive endocytosis of the immunocomplexed vaccine. In addition, C3b complement molecules formed by the complement activation process and which are attached to the immunocomplexed anti-Gal, further bind to C3b receptors (also called CR1) on APC and generate additional signals that increase endocytosis of the vaccine by APC (not shown).

Step 3

The vaccine internalized within endosomes of the APC is subjected to proteolytic activity of proteases that generate peptides of the viral proteins. These APC further migrate to the regional lymph nodes, process and present the vaccinating peptides in association with MHC molecules for effective activation of CD4⁺ and CD8⁺ T cells. The activated CD8⁺ T cells proliferate, leave the lymph nodes and circulate in order to detect and kill host cells containing the replicating virus. Activated CD4⁺ T cells proliferate and function as helper T cells that assist B cells in proliferation, isotype switching and maturation into antibody producing plasma cells. Activated CD4⁺ T cells also function as helper cells to CD8⁺ T cells maturing into CTL. In the absence of α -gal epitopes on the vaccinating virus, uptake by APC is likely to be suboptimal as it is mediated only by random pinocytosis.

This scenario is applicable to enveloped viruses and to their isolated viral envelope glycoproteins (including split or subunit vaccines or produced as recombinant glycoproteins) which can be glycoengineered to present α -gal epitopes on their glycans. In addition to the enzymatic method described below for *in vitro* synthesizing α -gal epitopes on vaccines, other methods for glycoengineering inactivated whole virus or viral glycoprotein vaccines to present α -gal epitopes are described at the end of this chapter.

Synthesis of α -Gal Epitopes on Viruses

The basic principle in the method of amplifying immunogenicity of viral vaccines presented in this chapter is the glycoengineering of the viral glycan shield for conversion of the multiple sialic acid epitopes into α -gal epitopes in order to prepare viral α -gal vaccines. Many of the glycans on envelope glycoproteins of viruses are asparagine (N)-linked glycans, synthesized on asparagines in amino acid sequences (sequon) asparagine-any amino acid-serine or threonine (N-X-S/T) (Vigerust & Shepherd, 2007). These glycans are synthesized by glycosylation enzymes (glycosyltransferases), mostly in the Golgi apparatus, in a sequential manner resembling an assembly line in a car plant. Part of the glycans are of the high-

mannose type having multiple mannose units and the rest are of the complex-type in which many the terminal carbohydrate units are “capped” with sialic acid (SA) as the left glycan in Figure 1. The enzyme neuraminidase (also called sialidase) in the first step (left reaction in Figure 1) cleaves the terminal SA from the SA-Gal β 1-4GlcNAc-R (sialyl-N-acetyllactosamine) carbohydrate sequence and exposes the penultimate N-acetyllactosamine (Gal β 1-4GlcNAc-R). The N-acetyllactosamine serves as acceptor for the α 1,3GT which links a galactose α 1-3 to the N-acetyllactosamine to form the α -gal epitope (second [right] reaction in Figure 1). The galactose is provided by the high energy sugar donor UDP-Gal. The second reaction, which is similar to the one in the Golgi apparatus of cells, is performed *in vitro* by recombinant (r) α 1,3GT (Chen et al. 2001). UDP-Gal may be purchased from commercial sources. In the case of inactivated influenza virus vaccine preparation, the envelope glycoprotein hemagglutinin (HA) does not have SA on its glycans. The SA of influenza virus is removed by the viral neuraminidase, thus the glycans of the complex type on HA have the center glycan structure in Figure 1. SA serves as a cellular docking receptor for the HA on influenza virus, and the removal of the autologous SA of the virus by neuraminidase has evolved in order to prevent the binding of HA on one virus to SA on the envelope of another virus. Thus, synthesis of α -gal epitopes on HA of influenza virus does not require the first reaction in Figure 1 (Henion et al. 1997).

Experimental Animal Model for Production of Anti-Gal and Amplification of Viral Vaccine Immunogenicity by This Antibody

The study of the hypothesis illustrated in Figure 3 requires the use of an experimental animal model that does not synthesize α -gal epitopes and thus, can produce the natural anti-Gal antibody. As indicated above, nonprimate mammals including lab animals such as mice, rats, guinea pigs and rabbits synthesize the α -gal epitope and thus are immunotolerant to it and cannot produce the anti-Gal antibody. However, mice suitable for this purpose are the GT-KO mice which lack α -gal epitopes because of the disruption (i.e., knockout [KO]) of the α 1,3GT gene (Thall et al. 1995; Tearle et al. 1995). Since these mice are usually kept in sterile environment, they lack the GI bacteria which provide the carbohydrate antigens that stimulate the immune system to produce anti-Gal. Induction of these mice to produce anti-Gal is feasible by repeated immunization with xeno-glycoproteins presenting multiple α -gal epitopes, such as pig kidney membrane homogenate (Tanemura et al. 2000), or with rabbit red blood cell membranes (LaTemple et al. 1999). In addition to the use of anti-Gal producing GT-KO mice, GT-KO pigs may be used as a large animal model (size close to that of humans) for studying α -gal vaccines. These pigs lack α -gal epitopes because of disruption of their α 1,3GT gene (Lai et al. 2002; Phelps et al. 2003) and they naturally produce the anti-Gal antibody with characteristics similar to those of human anti-Gal (Dor et al. 2004; Fang et al. 2012; Galili, 2013b). No other nonprimate mammals have yet been engineered to lack α -gal epitopes. Thus, all other nonprimate mammals cannot produce anti-Gal and are not suitable for studying α -gal vaccines. However, α -gal vaccines may be studied also in Old World monkeys such as baboon, rhesus, and cynomolgus monkeys, all lacking α -gal epitopes and producing the natural anti-Gal antibody (Galili et al. 1987b, 1988b; Teranishi et al. 2002).

OVA CONTAINING α -GAL LIPOSOMES AS A MODEL FOR VIRAL α -GAL VACCINE

The study of the hypothesis presented in Figure 3 required the use of a vaccinating antigen that can be detected following endocytosis into APC and which includes an immunogenic peptide of known structure. Such a peptide should be detected by activation of T cells with the corresponding TCR that can engage the presented immunogenic peptide. These requirements could be fulfilled by studying the amplification of immunogenicity of chicken ovalbumin (OVA) as a vaccine model in anti-Gal producing GT-KO mice (Abdel-Motal et al. 2009b). OVA is a suitable antigen for detection of APC internalizing it and for identification of T cells activated by it because the most immunogenic peptide of OVA for CD8⁺ T cells in mice is the 8-amino acid peptide SIINFEKL (Rötzschke et al. 1991). A CD8⁺ T hybridoma cell line called B3Z with a TCR specific for SIINFEKL was generated (Shastri & Gonzalez, 1993). These B3Z cells are activated when they engage APC presenting SIINFEKL. B3Z cell activation can be detected by the subsequent activation of a β -galactosidase transgene *LacZ* under IL2 promoter. Since T cells secrete IL2 as a result of their activation, in activated B3Z cells the IL2 promoter of the *LacZ* transgene activates this gene to produce β -galactosidase. These intracellular activation events occur following binding of SIINFEKL presented on MHC class I of H-2bK^b (called here H-2b) of APC to the TCR on B3Z cells. The β -galactosidase produced following such activation hydrolyzes FITC-di- β -D-galactopyranoside (FDG) introduced into B3Z cells, resulting in labeling the cells by the released fluorescein. This labeling of activated B3Z cells can be detected by flow cytometry.

OVA is a protein that lacks N-linked glycans and thus, it cannot be glycoengineered to carry α -gal epitopes. Simulation of a virus presenting α -gal epitopes, having OVA as a major protein antigen that is targeted to APC by anti-Gal, was achieved by use of OVA encapsulated within liposomes that present multiple α -gal epitopes (Abdel-Motal et al. 2009b). These α -gal liposomes are prepared from phospholipids, cholesterol and glycolipids extracted from rabbit red blood cell membranes. They present $\sim 10^{15}$ α -gal epitopes/mg liposomes and thus, readily bind the anti-Gal antibody (Wigglesworth et al. 2011). Following the immunocomplexing with anti-Gal these liposomes were effectively internalized by dendritic cells and macrophages. Moreover, 24 hours following such *in vitro* uptake of the α -gal liposomes containing OVA (called OVA-liposomes) by dendritic cells, these APC readily activated B3Z hybridoma T cells (Abdel-Motal et al. 2009b). This indicated that within 24 hours, the internalized OVA in OVA-liposomes was processed and SIINFEKL presented on the APC in association with MHC class I.

The *in vivo* uptake and transport of OVA-liposomes to regional lymph nodes by APC could be studied by subcutaneous injection of OVA-liposomes into GT-KO mice, in the right thigh. A week later the inguinal lymph nodes (the right regional lymph nodes of the injection site) were harvested, minced and the cells within them were co-incubated for 24 hours with B3Z cells. APC processing and presenting SIINFEKL within these lymph nodes were expected to activate the B3Z cells. Such activated B3Z cells could be detected by flow cytometry, following gating for the hybridoma cell size. The activated B3Z cells were detected as cells double stained, green for hydrolyzed FDG and red for anti-CD8 antibody-PerCP labeling all the B3Z cells since they are CD8⁺ T hybridoma cells (Figure 4A).

Lymph nodes draining the vaccination site in three anti-Gal producing GT-KO mice that were injected with OVA-liposomes displayed high numbers of SIINFEKL presenting APC, as indicated by the activation of 14-24% B3Z cells. In contrast, whereas the opposite (left) inguinal lymph node cells, displayed activation of only 2.5-3.7% B3Z cells (Figure 4A). The presence of multiple APC presenting SIINFEKL in lymph nodes draining the vaccination site area depended on the presence of the anti-Gal antibody in the injected mouse. This was shown with wild-type (WT) mice. As indicated above, WT mice are incapable of producing the anti-Gal antibody, as they synthesize α -gal epitopes and thus they are immunotolerant to this carbohydrate antigen. Cells from lymph nodes draining the vaccination site in WT mice injected with OVA-liposomes activated only 2.2-3.1% B3Z cells. This activation level was only slightly higher than that measured in the opposite leg inguinal lymph nodes (Figure 4B).

The data on B3Z cell activation by APC in lymph nodes draining the vaccination site suggest that anti-Gal mediated targeting of the vaccine to APC greatly increases uptake and transport of the vaccine to regional lymph nodes, as well as the processing and presentation of vaccinating antigens by APC. This, in turn, amplifies the activation of T cells specific for the immunogenic vaccine peptides. The increased activation of T cells could be further demonstrated by ELISPOT with spleen lymphocytes from the immunized mice that were co-incubated with dendritic cells pulsed with SIINFEKL. In this assay, individual activated T cells are detected by their secretion of interferon- γ (IFN γ) which is captured as a spot on membranes lining cell culture wells and identified by staining with labeled anti-IFN γ antibodies.

Figure 4. *In vitro* quantification of APC internalizing anti-Gal opsonized OVA liposome vaccine by subsequent evaluation of B3Z hybridoma T cell activation with APC from regional lymph nodes. APC internalizing the OVA liposomes present SIINFEKL on class I MHC molecules and activate B3Z cells. Cells from inguinal lymph nodes (LN) draining the immunization site in the right thigh (side of injection) and in left thigh (opposite LN) were obtained from anti-Gal producing GT-KO mice and from wild type (WT) C57BL/6 mice. Activation by SIINFEKL was detected by flow cytometry of B3Z cells with hydrolyzed FDG. Inguinal lymph node cells were harvested 7 days after vaccination with 10 mg OVA-liposomes in the right thigh. From “*The natural anti-Gal antibody as foe turned friend in medicine*” by U. Galili, 2018, Elsevier/Academic Press, p. 164, after (Abdel-Motal et al. 2009b).

There were on average 20-fold more SIINFEKL specific T cells among splenocytes of GT-KO mice immunized with OVA-liposomes than among splenocytes obtained from WT mice receiving similar immunization (Abdel-Motal et al. 2009b). Accordingly, the proportion of CD8⁺ T cells binding pentamers of H-2b carrying SIINFEKL was higher in the immunized GT-KO mice than in immunized WT mice.

Figure 5. Anti-Gal mediated amplification of antibody (A) and CTL immune response (B) following immunization with OVA-liposomes in anti-Gal producing GT-KO mice (■) and WT mice (□). (A) Production of anti-OVA IgG antibodies was assayed by ELISA, (n=6 per group). (B) Anti-SIINFEKL CTL activity with EL4 cells pulsed with SIINFEKL as target cells. Cell cytotoxicity was assessed by chromium release assay. Results represent the mean of data from six mice per group). Modified from (Abdel-Motal et al. 2009b).

Functional B cell and CTL activities were markedly higher in anti-Gal producing GT-KO mice immunized with the OVA-liposomes than in immunized WT mice that lack this antibody. As shown in Figure 5A, the titer of anti-OVA antibodies (measured by ELISA with OVA as solid-phase antigen) was found to be ~30-fold higher in GT-KO mice immunized with OVA-liposomes than in WT mice after similar immunization. Furthermore, cytotoxicity of target cells pulsed with SIINFEKL by CTL obtained from GT-KO mice immunized with OVA liposomes was >4 fold higher than cytotoxicity by CTL from WT mice (Figure 5B). These observations indicate that the elevated uptake of OVA-liposomes opsonized by anti-Gal and the increased transport of the internalized OVA by APC to regional lymph nodes, ultimately result in amplification of both cellular and humoral immune responses against the vaccinating protein. In sections below, the amplification of vaccine immunogenicity is further demonstrated with α -gal vaccines consisting of inactivated whole virus and vaccines containing recombinant enveloped virus glycoprotein.

INCREASED EFFICACY OF INFLUENZA VIRUS α -GAL VACCINE

Influenza virus appears around the world in yearly outbreaks that lead to 3-5 million cases of severe infections and >290,000 deaths (Iuliano et al. 2018). The major glycoprotein on the virus envelope is hemagglutinin (HA). The core of the virus contains 8 segments of negative sense RNA, each containing at least one gene. The virus spreads fast by human to human transmission. The HA glycoprotein on this virus mediates adhesion of the virus to

sialic acid on cell surface glycans. Based on the annual number of individuals displaying infection by the virus despite vaccination, it seems that presently used influenza vaccines fail to protect as many as 50% of vaccinated individuals from infection by the virus (Couch et al., 1997; Webster, 2000; Katz et al., 2004; Chang et al. 2012). Thus, more effective influenza vaccines are needed to be developed, in particularly for elderly individuals. Development of more effective vaccines is also needed in view of the risk of occasional appearance of influenza virus strains presenting new antigens on the viral envelope HA and neuraminidase. Pandemics caused by new influenza virus strains require the production of highly immunogenic vaccines that will protect individuals of all ages because all humans lack previous exposure to the new viral antigens. This section describes experiments demonstrating as much as 100 fold increase in immunogenicity of influenza inactivated whole virus vaccine glycoengineered to present multiple α -gal epitopes and studied in anti-Gal producing GT-KO mice. The influenza virus A/Puerto Rico/8/34- H1N1 (PR8 virus- adapted to work with mice) was used for these studies.

The HA glycoprotein of influenza virus has 6-8 glycans capped with N-acetyllactosamine (Gal β 1-4GlcNAc-R) as the center glycan in Figure 1 (Matsumoto et al. 1983; Kiel et al. 1985). This is the structure of the viral glycans when the virus is propagated in embryonated chicken eggs (lacking α 1,3GT). The glycans lack sialic acid because the viral neuraminidase on the virus envelope cleaves the terminal sialic acid off the HA glycans. However, when the PR8 virus was propagated in bovine cells (Madin-Darby bovine kidney (MDBK) cells) or in canine cells (Madin-Darby canine kidney (MDCK) cells), some of its HA glycans were capped with the α -gal epitopes as in the right glycan in Figure 1 (Galili et al. 1996). These epitopes were synthesized on the HA glycans because both cell types have active α 1,3GT enzyme (Galili et al. 1988b). Inactivated viruses produced in chicken, bovine and canine cells were studied for anti-Gal mediated uptake by APC according to the hypothesis illustrated in Figure 3. The uptake was assessed by activation of an HA specific T cell clone which has TCR specifically recognizing processed HA peptides presented on the APC. *In vitro* immunocomplexing of human anti-Gal with inactivated PR8 virus presenting α -gal epitopes resulted in increased uptake by APC. This was demonstrated by the ~10-fold increase in subsequent activation of the HA specific T cell clone by processed peptides presented on the APC, in comparison with activation of these HA specific T cells in the absence of anti-Gal (Galili et al., 1996). However, incubation of inactivated influenza virus produced in embryonated chicken eggs, with anti-Gal and APC resulted in subsequent uptake, processing and presentation of viral peptides by APC which was similar to that observed in the absence of anti-Gal. These findings indicated that presence of α -gal epitopes on vaccinating influenza virus enables formation of immune complexes with anti-Gal, resulting in more effective uptake of the vaccine by APC than the random pinocytosis of the vaccine in the absence of α -gal epitopes.

It could be argued that producing influenza virus for vaccine preparation in MDCK or MDBK may suffice for preparation of a vaccine presenting α -gal epitopes that will be effectively targeted by anti-Gal to APC. However, the number of α -gal epitopes on influenza virus replicating in these cells seems to be far from optimal for effective *in vivo* targeting to APC. The number of such epitopes on MDCK cells is ~10 fold lower than that on MDBK cells and may be less than one per glycan (Galili et al. 1996). This low presentation of α -gal epitopes may explain why the efficacy of MDCK produced vaccine is not significantly

different from that of vaccine produced in chicken cells (Ambrozaitis et al. 2009; Szymczakiewicz-Multanowska et al. 2009).

Propagation of influenza virus (as well as other enveloped viruses) in available cell lines cannot reach a maximum number of α -gal epitopes (i.e., on each of the 2-4 branches (antennae) of the glycan), because of competition between α 1,3GT and other glycosyltransferases (in particular sialyltransferases) in the Golgi apparatus. The last step in the glycosylation process of cellular and viral glycans occurs in the trans-Golgi compartment where in nonprimate mammalian cells α 1,3GT and other glycosyltransferases (mostly sialyltransferases) compete for capping the nascent glycan with Gal α 1-3 to form α -gal epitopes, as in the right glycan of Figure 1, or with sialic acid to form the left glycan in Figure 1 (Smith et al. 1990). The final makeup (profile) of glycans on host cells and on viruses replicating in them depends on the concentration and relative activities of α 1,3GT and sialyltransferases (as well as other glycosyltransferases) in the trans-Golgi. Sections at the end of this chapter describes several glycoengineering methods which can maximize the number of α -gal epitopes on vaccinating viruses. One of the methods which has been tried and shown to markedly increase immunogenicity of influenza virus vaccine due to extensive targeting of α -gal vaccines by anti-Gal to APC, uses recombinant α 1,3GT (α 1,3GT) for *in vitro* synthesis of α -gal epitopes on the vaccinating virus (Abdel-Motal et al. 2007). The α 1,3GT was cloned from New World monkey cDNA as a truncated gene lacking the cytoplasmic and trans-membrane domains and was produced first in mosquito SF9 cell line expression system (Henion et al. 1994) and later in the yeast *Pichia pastoris* expression system (Chen et al. 2001).

The PR8 virus was precipitated from the allantoic fluid of embryonated chicken eggs by polyethyleneglycol and purified on a continuous sucrose gradient (Galili et al., 1996). The virus was inactivated by incubation for 45 min in 65°C and confirmed for complete inactivation by the loss of hemagglutinating activity with chicken red blood cells (RBC). The virus was subjected to *de novo* synthesis of α -gal epitopes according to the second enzymatic reaction in Figure 1 in which PR8 virus (100 μ g/ml) was incubated with α 1,3GT (30 μ g/ml) and UDP-Gal (1mM) in the presence of Mn⁺⁺ for 2 hours at 37°C. Control PR8 virus was incubated under similar conditions with inactivated α 1,3GT (10 min incubation in boiling water) and with 1mM UDP-Gal (Henion et al. 1997; Abdel-Motal et al. 2007). The enzymatic reaction resulted in the synthesis of ~3000 α -gal epitopes on the inactivated PR8 virus (referred to as PR8 _{α gal}), but not on the control PR8 virus. Western blot analysis of the α -galactosylated glycoproteins separated by SDS-PAGE electrophoresis under reducing conditions indicated that the synthesis of α -gal epitopes was mainly on the glycans of the HA₁ molecule, which is the distal portion of the HA molecule (Figure 6). The α -gal epitopes on HA₁ bound both serum anti-Gal produced in GT-KO mice and monoclonal anti-Gal M86 (Abdel-Motal et al. 2007).

In order to determine whether the immunogenicity of PR8 _{α gal} differs from that of PR8, anti-Gal producing GT-KO mice received two immunizations in two-week interval of either 1 μ g of inactivated PR8 _{α gal}, or a similar amount of inactivated PR8 virus. The Ribi adjuvant was administered with the vaccine. The immune response to the vaccine was determined two weeks after the second vaccination. The number of T cells activated by the vaccination was determined by production of interferon- γ (IFN γ) into two types of assays: 1. ELISPOT

measuring secretion of IFN γ from individual cells, and 2. Intracellular staining (ICS) measuring by flow cytometry the proportion of cells that are positively stained for production of IFN γ , characteristic to activated CD4 $^{+}$ and CD8 $^{+}$ T cells. In the ELISPOT assay, four of the six mice immunized with PR8 $_{\alpha\text{gal}}$ inactivated virus displayed ~ 2200 T cells secreting IFN γ per 10^6 spleen cells, whereas mice immunized with PR8 inactivated virus displayed only ~ 600 IFN γ secreting T cells per 10^6 cells (Abdel-Motal et al. 2007).

Figure 6. Glycoengineering of PR8 influenza virus to present α -gal epitopes. α -Gal epitopes on PR8 $_{\alpha\text{gal}}$ were demonstrated by Western blots stained with anti-Gal antibody purified from GT-KO mouse serum and with monoclonal anti-Gal M86 (Galili et al. 1998). Note that both anti-Gal antibodies bind to HA1 from PR8 $_{\alpha\text{gal}}$ and not to the HA1 from unprocessed PR8. A representative study of three independent studies with similar results. From (Abdel-Motal et al. 2007).

ICS evaluation of IFN γ production demonstrated on average $\sim 21\%$ of cells with positive staining among CD8 $^{+}$ T cells of the four out of six PR8 $_{\alpha\text{gal}}$ immunized mice vs. $\sim 3.5\%$ of CD8 $^{+}$ cells in PR8 immunized mice (Figure 7A). Similarly, $\sim 13\%$ of the CD4 $^{+}$ T cells from PR8 $_{\alpha\text{gal}}$ immunized mice stained positively for intracellular IFN γ vs. $\sim 0.1\%$ of CD4 $^{+}$ cells in PR8 immunized mice (Figure 7B). The remaining two mice immunized with PR8 $_{\alpha\text{gal}}$ (#5 and #6) assayed in both ELISPOT and ICS analyses displayed similar numbers of IFN γ producing T cells as those in PR8 immunized mice (#11 and #12).

The immunization of anti-Gal producing GT-KO mice with PR8 $_{\alpha\text{gal}}$ inactivated virus also resulted in a much higher production of anti-PR8 antibodies in comparison to mice immunized with inactivated PR8 virus lacking α -gal epitopes (i.e., virus serving as an antigenic source for some of the present day used vaccines). The activity of anti-PR8 antibodies was measured by ELISA in which PR8 virus served as solid-phase antigen attached to ELISA wells by drying aliquots of virus suspension. The titer of anti-PR8 IgG antibodies (defined as serum dilution yielding 1.0 O.D. in ELISA) was ~ 100 -fold higher in PR8 $_{\alpha\text{gal}}$ immunized GT-KO mice than in the mice immunized with inactivated PR8 virus (Figure 8A). In four of the PR8 $_{\alpha\text{gal}}$ immunized mice, anti-PR8 production was much higher than in the remaining two mice which also displayed low T cell response in Figure 7.

Figure 7. Intracellular staining (ICS) of IFN γ in CD8 $^{+}$ (A) and CD4 $^{+}$ T cells (B) in PR8 $_{\text{agal}}$ or PR8 immunized, anti-Gal producing GT-KO mice. ICS analysis in CD8 $^{+}$ T cells (A including two left panels) and CD4 $^{+}$ T cells (B including two right panels) in PR8 $_{\text{agal}}$, or PR8 immunized mice (n=6 per group). Lymphocytes were gated in (A) for CD8 $^{+}$ and in (B) for CD4 $^{+}$ membrane markers and analyzed for IFN γ production. Lymphocytes were obtained 14 days after the second immunization and incubated overnight with dendritic cells prepulsed with inactivated PR8. From (Abdel-Motal et al. 2007).

Figure 8. Production of anti-PR8 antibodies in immunized mice. Mice were immunized twice with 1 μ g inactivated PR8 $_{\text{agal}}$ (●), or with 1 μ g inactivated PR8 (○). Both vaccines also included Ribi adjuvant. Production of anti-PR8 antibodies was measured by ELISA with PR8 virus as solid phase antigen. (A) Anti-PR8 IgG antibodies in anti-Gal producing GT-KO mice. (B) Anti-PR8 IgG response in wild type (WT) mice. (n=6 per group). From (Abdel-Motal et al. 2007).

The importance of anti-Gal as the antibody targeting the immunocomplexed virus to APC could be evaluated by repeating the experiment of Figure 8A in wild type (WT) C57BL/6 mice. These mice lack anti-Gal despite immunization with pig kidney membranes because the α -gal epitope is a self-antigen in them. No difference in anti-PR8 titer was observed between PR8 $_{\alpha\text{gal}}$ immunized and PR8 immunized mice. In both groups, anti-PR8 antibodies were produced at a similar low titer that was 80-100 fold lower than that in PR8 $_{\alpha\text{gal}}$ immunized GT-KO mice (Figure 8B).

The anti-viral activity of these antibodies was further studied by determining the ability of the antibodies to block binding of HA on the virus to its docking receptor, the sialic acid on cell surface glycans. This is performed by studying the inhibition of hemagglutination of chicken RBC by the PR8 virus. The virus was incubated with serum at serial two fold dilutions of the serum. The RBC (1%) were added to the virus incubated in the serum and hemagglutination inhibition was determined after 30 min. Sera of PR8 $_{\alpha\text{gal}}$ immunized mice that displayed high anti-PR8 IgG antibody activity were found to be >10 fold more potent in inhibiting hemagglutination than sera from PR8 immunized mice (Abdel-Motal et al. 2007). This implies that a significant proportion of the anti-PR8 antibodies produced in PR8 $_{\alpha\text{gal}}$ immunized mice bind to HA and inhibit its biological activity that enables infection of cells.

The secretory IgA antibody against influenza virus is considered to be the primary antibody involved in protecting mucosal surfaces of the respiratory tract against infection by this virus (Kiyono et al. 2008). Therefore, it was of interest to determine if there is a difference in anti-PR8 IgA antibody production in PR8 $_{\alpha\text{gal}}$ vs. PR8 immunized mice. ELISA studies for anti-PR8 IgA antibodies in the serum of vaccinated mice were performed by the same method as that presented in Figure 8 for anti-PR8 IgG, using anti-mouse IgA-HRP as a secondary antibody (Figure 9A). These studies demonstrated high titers of anti-PR8 IgA (1:800 to 1:6400) in four of the six mice immunized with PR8 $_{\alpha\text{gal}}$ that also displayed high T cell response to PR8 antigens in Figure 7 and high anti-PR8 IgG antibodies in Figure 8A. In contrast, mice immunized with PR8 displayed anti-PR8 IgA titers of <1:50.

Figure 9. Anti-PR8 IgA antibodies in serum (A) and in lungs (B) of mice immunized with PR8 $_{\alpha\text{gal}}$ (●) vs. PR8 vaccine (○). (A) Antibody production in the serum of anti-Gal producing GT-KO mice. The two lowest PR8 $_{\alpha\text{gal}}$ immunized GT-KO mice producing anti-PR8 IgA are the same as mice #5 and #6 in Figure 7 and also producing the lowest anti-PR8 IgG. (B) Anti-PR8 IgA antibodies in lungs of immunized mice (n=6 per group). From (Abdel-Motal et al. 2007).

Study of anti-PR8 IgA antibodies in supernatants prepared from homogenates of lungs obtained from the immunized mice demonstrated the presence of these antibodies in lungs of PR8_{αgal} immunized mice, whereas lungs of mice immunized with PR8 lacked detectable amounts of these IgA antibodies (Figure 9B) (Abdel-Motal et al. 2007). This finding indicated that in addition to amplification of the immune response against the virus within the serum of mice vaccinated with whole virus α-gal vaccine, this vaccination enables the production of anti-virus IgA antibodies that are secreted into the respiratory tract of vaccinated mice. As further shown below, these secreted antibodies are likely to protect the cells lining the respiratory tract from infection by inhaled influenza virus. These observations suggest that the use of viral α-gal vaccines may be of similar significance in prophylactic immunization of individuals against other viruses capable of infecting the respiratory tract such as SARS-CoV-2 that is the pathogen causing COVID-19 respiratory disease (Galili 2020b).

In order to determine whether the antibodies produced following immunization with PR8_{αgal} affect the replication of the virus in the respiratory tract, immunized mice were challenged by intranasal application of 2000 plaque forming units (PFU) of infectious PR8 virus, 14 days after the second immunization. This challenge dose is lethal for 100% of non-immunized infected mice. The mice were euthanized three days post intranasal challenge, lungs harvested and homogenized in PBS in a total volume of 1ml. The virus was quantified in the suspension by measuring the tissue culture infectious dose (TCID) in MDCK cell monolayers at serial dilutions of the supernatant and determining the reciprocal of the highest dilution displaying cytopathic effect. The TCID of lung homogenate in two PR8_{αgal} immunized mice was 100 and the remaining 3 mice had TCID of 10, i.e., lung supernatant dilution of 1:10 was the highest dilution displaying a cytopathic effect on MDCK cells (Figure 10A). In contrast, in PR8 immunized mice, four of the five mice displayed TCID of 1000 and the fifth displayed TCID of 100. The average TCID among PR8_{αgal} immunized mice was ~18 fold lower than that among PR8 immunized mice. Thus, the number of virus particles in the lungs of PR8_{αgal} immunized mice was ~5% of that in PR8 immunized mice, suggesting that the majority of the virus in the challenge was neutralized and destroyed in the former group (Abdel-Motal et al. 2007). A second method of measurement PR8 presence in the lungs was hemagglutination of chicken RBC at various dilutions of the supernatant. The hemagglutination titers (reciprocal of end point dilution displaying hemagglutination) in four PR8_{αgal} immunized mice was 50 and in the fifth it was 100 (Figure 10B). In contrast, in PR8 immunized mice the titer in lungs of three mice was 1000 and in the remaining two mice it was 10,000, thus supporting the TCID observations on the much lower viral load in the lungs of the PR8_{αgal} immunized mice than in the PR8 immunized mice.

The ultimate test for evaluating the efficacy of PR8_{αgal} vs. PR8 vaccines is the protection in preventing death of the immunized mice following intranasal challenge by a lethal dose (2000 PFU) of infectious PR8 virus. Survival was monitored for 30 days following that challenge of mice (n=25 per group). Most mice (88%) immunized with inactivated PR8 virus succumbed to the PR8 infection and died by Day 10 post challenge (Figure 11). The survival of three out of 25 mice immunized with PR8 vaccine, vs. the death of all nonimmunized mice infected with the infectious virus implies that this vaccine has suboptimal efficacy, protecting only ~12% of the immunized mice. In contrast to PR8 immunized mice, mice immunized with inactivated PR8_{αgal} virus were much more resistant to the challenge. Only 12% of the

mice died following the viral infection and the remaining 88% survived. Survival data on Day 30 were the same as on Day 15 in Figure 11.

Figure 10. Virus quantification following intranasal challenge by a lethal dose of PR8 influenza virus in anti-Gal producing GT-KO mice immunized with inactivated PR8 α gal or PR8 virus. (A) Analysis of virus titer as tissue culture infectious dose (TCID) in lungs of the challenged mice, 3 days post challenge (n=5 per group). Supernatants of lung homogenates were incubated in serial 10 fold dilutions in 96 well plates with MDCK cell monolayers. Cytopathic effects were scored after 96 hours. (B) PR8 virus titers in lungs of GT-KO mice, 3 days post challenges as assessed by hemagglutination of chicken RBC. The virus titers were assayed in supernatants of lung homogenates (n=5 per group). From (Abdel-Motal et al. 2007).

Figure 11. Survival of mice immunized with inactivated PR8 or PR8 α gal virus, following intranasal challenge with lethal dose of fresh infectious PR8 influenza virus. Anti-Gal producing GT-KO mice were immunized twice with 1 μ g inactivated PR8 (O), or with PR8 α gal (●) whole virus vaccines. Mice were subsequently challenged with 2000 PFU of infectious PR8 virus, 14 days after the second immunization (n=25 per group). Data presented as % of infected mice at various days. Survival data on Day 30 were the same as on Day 15 post challenge. From (Abdel-Motal et al. 2007).

Overall, the studies with the PR8 virus provide a proof of principle for the hypothesis illustrated in Figure 3, as they demonstrate a much higher protection from a lethal dose virus infection in mice immunized with a glycoengineered whole virus α -gal vaccine than in mice immunized with vaccine of the original virus lacking α -gal epitopes. This higher protection is associated with a higher activation of virus specific T cells and a much higher production anti-viral IgG and IgA antibodies. A recent study has demonstrated increased resistance to challenge by infectious influenza virus in GT-KO mice that were immunized with attenuated influenza virus containing the α 1,3GT transgene and thus presenting α -gal epitopes synthesized by α 1,3GT coded by this gene (Yan et al. 2020). All these studies suggest that vaccination of humans with virus presenting α -gal epitopes (i.e., α -gal vaccine) may confer a much higher protection upon exposure to infectious virus than virus vaccines that present the original unmodified glycan shield. In view of the current use of several viral envelope glycoprotein vaccines in the form of split, subunit or recombinant proteins, the studies with the inactivated PR8 _{α gal} whole virus vaccines raised the question whether a similar anti-Gal mediated amplification of vaccine immunogenicity can be achieved with the isolated envelope glycoprotein or with recombinant viral glycoprotein vaccines. Studies on this issue are described in the section below. with recombinant gp120 of HIV as vaccine.

INCREASED IMMUNOGENICITY OF HIV-GP120 PRESENTING α -GAL EPI- TOPES AS A RECOMBINANT GLYCOPROTEIN VACCINE MODEL

Immunogenicity analysis of an α -gal vaccine consisting of a viral glycoprotein was performed with the major envelope glycoprotein gp120 of human immunodeficiency virus (HIV). This glycoprotein produced as recombinant gp120 of the HIV_{BAL} strain in Chinese Hamster Ovary (CHO) cells that were transformed with the corresponding codon optimized *env* gene. The interest in this glycoprotein stems from the fact that recombinant HIV vaccines trials in primate models and in clinical trials were found to display only suboptimal efficacy in eliciting a sterilizing protective immune response against infection with HIV or with simian immunodeficiency virus (SIV) (Berzofsky et al. 2004; Goulder & Watkins, 2004; Pantaleo & Koup, 2004; Letvin, 2005; Munier et al. 2011). It is expected that an effective prophylactic HIV vaccine should induce a strong protective memory immune response that produces neutralizing antibodies and cytotoxic T-lymphocyte (CTL) response. Combination of these two types of immune response should prevent binding of HIV to its receptors on cells, thereby inhibit infection of cells by neutralizing anti-gp120 antibodies and induce effective detection of infected host cells for their destruction by CTL. Such an immune response should be effective in early stages following transmission of the virus, when the number of infected cells is relatively low, in order to prevent the virus from expanding and reaching a lethal mass. In addition to prevention of extensive virus replication within host cells of the infected individual, a rapid immune response will prevent the virus from undergoing mutations in envelope glycoproteins that enable HIV to evade the neutralizing antibodies without losing receptor binding activity (Wei et al. 2003; Crooks et al. 2015).

Gp120 of HIV mediates binding of the virus to specific receptors. This glycoprotein has 479 amino acids and carries a glycan shield of 24 N-linked glycans of which 13-16 are of the complex type capped with sialic acid (SA) (left chain in Figure 1), and the rest are of the high-mannose type (Geyer et al. 1988; Mizuochi et al. 1988; 1990; Leonard et al. 1990). The glycans of gp120 have a size of approximately ~ 60 Å, which is $\sim 30\%$ of the diameter of the protein portion of the gp120 molecule in its globular form. Because of the relatively large size of the glycan, the glycan shield comprised of 24 glycans can mask a significant proportion of the immunogenic gp120 peptides, thus resulting in decreased efficacy of gp120 vaccine (Wei et al. 2003). In addition, multiple negative charges surrounding the gp120 vaccine are provided by many SA units capping the N-linked glycan of the complex type. These negative charges induce electrostatic repulsion (ζ -potential) which decreases the uptake of vaccinating glycoprotein molecules, as illustrated in Figure 2A. The protective effects of the multiple glycans of the glycan shield in evasion of HIV from the immune response can be inferred from isolate clones of HIV type 1 (HIV-1) in AIDS patients, where at least half of the mutations in gp120 (i.e., the *env* gene) form new N-glycosylation sites (i.e., Asn-X-Ser/Thr sequon) which increase the size of the glycan shield that protects the virus from neutralizing antibodies (Wei et al. 2003).

All these considerations on the role of the glycan shield in minimizing the immunogenicity of gp120 led to the assumption that glycoengineering this glycoprotein by synthesizing α -gal epitopes on its glycans may increase its immunogenicity according the hypothesis illustrated in Figure 3. It was hypothesized that immunization with gp120 _{α gal} will elicit a much stronger anti-gp120 immune response than immunization with the original gp120 lacking α -gal epitopes, as the result of effective anti-Gal mediated targeting of the immunizing glycoprotein to APC.

Synthesis of α -Gal Epitopes on gp120

Glycoengineering gp120 into gp120 _{α gal} is achieved by a two-step enzymatic reaction combining the activities of neuraminidase and $\alpha 1,3$ GT, as describe in Figure 1. For performing these studies, recombinant gp120 of the HIV_{BAL} strain was produced in CHO cells and provided as a generous gift from the NIH AIDS Research and Reference Reagent Program. It should be stressed that CHO cells lack active $\alpha 1,3$ GT (Smith et al. 1990), although they originate in hamster, which like other nonprimate mammals, has active $\alpha 1,3$ GT synthesizing α -gal epitopes (Galili et al. 1988b). It is possible that CHO cells were grown in the 1950s in culture medium containing human serum and the anti-Gal in the human serum selected for growth of CHO cells devoid of α -gal epitopes. Neuraminidase was purified from *Vibrio cholerae* and recombinant $\alpha 1,3$ GT was produced in the *Pichia pastoris* expression system (Chen et al. 2001).

The glycans on gp120 differ from those on HA of influenza virus in that gp120 has SA capping the glycan (left carbohydrate chain in Figure 1). In contrast the influenza virus HA lacks SA because SA that caps the glycan in the Golgi apparatus is cleaved off the glycan by viral neuraminidase. The absence of SA (center glycan in Figure 1) enables synthesis of α -gal epitopes by $\alpha 1,3$ GT on the desialylated glycans to generated gp120 _{α gal} (second enzymatic

reaction in Figure 1). These two enzymatic reactions of SA cleaving and synthesis of α -gal epitopes on gp120 could be performed in one solution containing neuraminidase, α 1,3GT and UDP-Gal, as well as Mn^{++} cations that are required for α 1,3GT catalytic activity (Abdel-Motal et al. 2006). Isolation of gp120 _{α gal} from the rest of reaction mixture components is feasible by the use of an affinity agarose column with coupled *Bandeiraea (Griffonia) simplicifolia* IB4 (BS lectin). This lectin binds α -gal epitopes (Wood et al., 1979) and thus specifically binds only gp120 _{α gal} and no other molecules or ions in the reaction mixture. After washing the column, the bound gp120 _{α gal} can be eluted by galactose, α -methyl galactoside, or melibiose solution passed through the column. The specific binding of both human anti-Gal and mouse anti-Gal to the gp120 _{α gal} and not to the original gp120 is shown in Figure 16 in the section discussing the similarities between human and mouse anti-Gal antibodies regarding their ability to bind to α -gal viral vaccines.

Amplification of Anti-HIV Immune Response Following Immunization with gp120 _{α gal} vs. gp120 Vaccines

As in the studies above on PR8 _{α gal} and α -gal OVA-liposomes, the analysis of gp120 _{α gal} immunogenicity vs. that of gp120 was performed in anti-Gal producing GT-KO mice. These mice were immunized subcutaneously twice with 5 μ g gp120 or gp120 _{α gal} and Ribi adjuvant, in 2 week interval (Abdel-Motal et al. 2006). The immune response was evaluated 17 days after the second immunization. Assessment of the gp120 specific T cell response in the immunized mice was determined by quantification of IFN γ secreting activated T cells among splenocytes co-incubated with dendritic cells pulsed with gp120 in a 24 hour ELISPOT assay. Each T cell secreting IFN γ is detected as a spot in this assay since the secreted IFN γ binds to anti-IFN γ coating membranes lining the wells and is subsequently identified by a labeled anti-IFN γ -peroxidase antibody. The clear visual difference in the number of spots generated by this T cell activation is demonstrated in Figure 12A which shows the triplicate wells with splenocytes from three representative mice per each group.

Practically, no spots indicating spontaneous secretion of IFN γ were observed in the absence of pulsing gp120 as the *in vitro* stimulatory antigen. However, in the presence of gp120 as the activating antigen in the ELISPOT wells, the numbers of IFN γ secreting T cells in gp120 _{α gal} immunized mice were visually much higher than those in gp120 immunized mice (Figure 12A). Figure 12B describes the average number of spots representing activated T cells secreting IFN γ in the 6 mice evaluated in each group. Whereas mice immunized with gp120 displayed on average 23 spots (i.e., 23 gp120 specific activated T cells per 10⁶ cells incubated in each well in the presence of gp120), mice immunized with gp120 _{α gal} displayed ~15 fold higher number of gp120 specific activated T cells, i.e., 332 spots per 10⁶ cells (Abdel-Motal et al. 2006).

In addition to the higher gp120 specific T cell activation following immunization with gp120 _{α gal}, the antibody production against gp120 was much higher post immunization with gp120 _{α gal} than post immunization with the original gp120 lacking α -gal epitopes. Production of anti-gp120 antibody was measured in 5 mice in each group by ELISA with gp120 as solid-

phase antigen. The vast difference in production of anti-gp120 IgG antibodies is clearly observed in Figure 13A.

Figure 12. Identification of gp120 specific T cells in anti-Gal producing GT-KO mice immunized with gp120, or gp120_{gal} as assessed by ELISPOT analysis for IFN γ secretion. (A) Photos of spots in wells with splenocytes from three mice, each tested in triplicates wells (vertical lanes) which lacked (control wells) or contained gp120 pulsed dendritic cells. (B) Mean number of spots per well from six individual mice in each of the two groups (mean of spots in triplicate wells for each mouse). Modified from (Abdel-Motal et al. 2006).

Figure 13. Anti-gp120 IgG production in mice following immunization with gp120 (O) or gp120_{gal} (●). (A) Anti-gp120 antibody production in anti-Gal producing GT-KO mice immunized twice with either 5 μ g gp120 vaccine, or with 5 μ g gp120_{gal} vaccine. (B) Anti-gp120 antibody production in wild type mice (WT) immunized as in Figure 13A. From (Abdel-Motal et al. 2006).

Anti-gp120 antibody activity in mice immunized with gp120 _{α gal} was 100-200 fold higher than in mice immunized with gp120 (Abdel-Motal et al. 2006). The much higher production of anti-gp120 antibodies was dependent on the presence of the anti-Gal antibody which forms immune complexes with gp120 _{α gal} and not with gp120. This is demonstrated in Figure 13B in which the same vaccination as in Figure 13A was performed in wild-type (WT) mice which lack the anti-Gal antibody despite repeated immunizations with pig kidney membranes. All groups received a similar number of immunizations with pig kidney membranes homogenate for eliciting anti-Gal production. Anti-gp120 antibody production in WT mice was low and similar in both groups of mice indicating that the presence of α -gal epitopes on the immunizing gp120 _{α gal} vaccine resulted in no amplification of the antibody response in the absence of anti-Gal. A similar marked increase in antibody and T cell response was observed with antibodies to bovine serum albumin (BSA) in GT-KO mice immunized with BSA _{α gal} in comparison to those immunized with BSA, as well as with CTL killing tumor cells presenting viral antigens (Benatuil et al. 2005).

The ultimate objective of vaccination for production of anti-gp120 antibodies is protection of the vaccinated individuals by antibodies that can neutralize HIV, thus preventing HIV infection of host cells. The neutralizing potential of anti-gp120 antibodies produced in mice immunized with gp120 _{α gal} was determined in comparison to antibodies produced in gp120 immunized mice. For this study, the HIV-1 lab strain MN was tested for infectivity of cells following incubation with sera from the two groups, at serial dilutions of the sera. The extent of neutralization was measured by the prevention of T cell killing by the HIV_{MN} in a killing assay of the human T-cell lymphoma line MT-2 infected by the virus (Montefiori et al. 1996; Wang et al. 2005). The HIV_{MN} virus used for mediating killing of the infected T cells is a strain which is convenient for work in the lab and its gp120 amino acid sequence differs by only few amino acids from that of gp120 of HIV_{BAL} (the source for the vaccinating gp120). Thus, it is assumed that anti-gp120 antibodies mediated prevention of MT-2 cell killing by HIV_{MN} would serve as a positive conservative result on even higher neutralizing effect of the anti-gp120 antibodies on HIV_{BAL} infecting T cells.

Figure 14. Evaluation of neutralizing antibody activity in anti-Gal producing GT-KO mice. Mice were immunized with gp120 (mice #1-#6), or with gp120 _{α gal} (mice #7-#12). Titer is defined as reciprocal of serum dilution displaying 50% neutralization. From (Abdel-Motal et al. 2006).

In accord with the low titers of anti-gp120 antibodies in sera of mice immunized with gp120 (Figure 13A), these sera displayed no neutralizing activity above that of the nonimmunized mice (mice #1 to #6 in Figure 14). In contrast, antibodies in sera of mice immunized with gp120_{αgal} (mice #7 to #12 in Figure 14) were found to display very effective neutralization activities, which were similar to that observed in the positive control of rabbit serum containing anti-HIV neutralizing antibodies (originating from a rabbit receiving multiple immunizations with gp120) (Wang et al., 2005).

These results demonstrate a correlation between the high titer of anti-gp120 antibody production as a result of immunization with gp120_{αgal} and the neutralizing activity of the elicited antibodies. Overall, the findings on the immune response in mice immunized with gp120_{αgal} vs. mice immunized with gp120 suggest that both T cell activation against the gp120 peptides and antibody production against gp120 are much higher in mice that were immunized with recombinant envelope glycoprotein α-gal vaccine than in mice immunized with recombinant envelope glycoprotein vaccine lacking α-gal epitopes. These findings are in line with the vaccine studies using a whole inactivated influenza virus vaccine glycoengineered to present α-gal epitopes. These results raise the possibility that glycoengineering of inactivated whole virus, subunit glycoprotein, and of recombinant viral glycoprotein vaccines for their conversion into α-gal vaccines may serve as a general method for increasing viral vaccine immunogenicity by altering their glycan shield from part of the envelope glycoprotein that protects the virus against the immune system to a component of the vaccine that effectively targets it to APC by immunocomplexing with the natural anti-Gal antibody.

TARGETING OF LOW IMMUNOGENICITY HIV PROTEINS TO APC BY FUSION WITH GP120_{αGAL}

Studies on possible changes in HIV in the course of infection in humans demonstrated the occurrence of mutations in the envelope glycoprotein gp120 which enable the virus to evade the neutralizing and destructive effects of antibodies produced against the virus replicating in the patients (Wei et al. 2003; Crooks et al. 2015). Therefore, it is assumed that vaccination only with gp120 may not elicit an immune response against HIV infections that is effective enough to protect large populations against human to human transmission of this virus (Goulder and Watkins, 2004; Lewis et al. 2014). In contrast, the internal proteins of HIV, such as tat, rev, p17 or p24, do not mutate in course of HIV infection, probably because of functional constraints that prevent viruses with such mutations from further replication. Thus, these internal proteins may serve as effective vaccines that elicit a cellular immune response which can destroy HIV infected cells by CTL. It has been assumed that increased immunogenicity of vaccinating internal HIV proteins may be achieved by effective targeting of such vaccines to APC. These proteins cannot be glycoengineered to present α-gal epitopes because they carry no glycans. Thus, it was hypothesized that fusion of such internal proteins with gp120 and subsequent glycoengineering of the gp120 glycans to present α-gal epitopes may result in increased targeting to APC of internal protein fused to glycoengineered gp120 (Abdel-Motal et al. 2010). In order to test this assumption, the core (capsid) protein p24 was

chosen as a model protein and was fused with gp120. The fused gp120/p24 protein was produced as a recombinant protein in a mammalian cell expression system and the glycan shield of the gp120 portion of the fused protein was engineered into presenting α -gal epitopes by the use of neuraminidase and α 1,3GT, as described above and in Figure 1, thus generating gp120 _{α gal}/p24 vaccine.

Production and Immunogenicity of gp120 _{α gal}/p24 Vaccine

In order to produce a fusion protein between gp120 and p24, the gene regions of *env* coding for gp120 and of *gag* coding for p24 were ligated as shown in Figure 15A (Abdel-Motal et al., 2010). The fused gene was inserted into a plasmid downstream from the strong CMV promoter. The fused gp120/p24 gene within the plasmid underwent transient transfection in human 293 cells which produced the gp120/p24 fusion protein in a secreted form. Following the isolation of the fusion protein from the culture medium by precipitation with ammonium sulfate, gp120/p24 was subjected to the two step enzymatic reaction with neuraminidase and α 1,3GT as illustrated in Figure 1. This synthesizes α -gal epitopes on the glycan shield of the fusion protein, thereby converting it into gp120 _{α gal}/p24. As indicated above, the p24 portion of the fusion protein lacks N-linked glycans and thus it lacks α -gal epitopes.

The immunogenicity of gp120 _{α gal}/p24 was compared to that of gp120/p24 by immunizing two groups of anti-Gal producing GT-KO mice with each of these two vaccines. Mice received two subcutaneous immunizations of gp120/p24 or gp120 _{α gal}/p24 in two-week interval. The vaccines were delivered at 5 μ g per injection with Ribi adjuvant. Two weeks after the second immunization the spleens of the mice were harvested and the splenocytes isolated from these spleens. The presence of T cells specific to p24 was determined by incubation with the p24 immunodominant peptide p24₁₈₉₋₂₀₇ (Qiu et al. 1999) which pulsed APC among the splenocytes. T cells with TCR specific to this peptide were activated within 24 hour coincubation with the APC pulsed with p24₁₈₉₋₂₀₇ and secreted IFN γ that could be detected for individual activated T cells by the ELISPOT assay. The number of T cells secreting IFN γ among lymphocytes from gp120 _{α gal}/p24 immunized mice was ~12 fold higher than the number of these cells in gp120/p24 immunized mice (Abdel-Motal et al., 2010). The proportion of p24 specific CD8⁺ T cells (T cells becoming CTL) was determined by double staining of cells binding anti-CD8 antibody and displaying intracellular staining of IFN γ . As shown in Figure 15B, mice immunized with gp120 _{α gal}/p24 displayed 5-20-fold higher number of CD8⁺ T cells with detectable production of IFN γ than mice immunized with gp120/p24 lacking α -gal epitopes. These findings imply that anti-Gal immunocomplexed with gp120 _{α gal}/p24 indeed markedly increased the immunogenicity of p24 in comparison to immunogenicity of p24 in the gp120/p24 fusion protein, probably because of the effective targeting to APC of the fused protein via Fc/Fc receptor interaction.

Studies above demonstrated increased immunogenicity of gp120 _{α gal} in comparison to gp120 (Figure 13A). Accordingly, immunization of anti-Gal producing mice with gp120 _{α gal}/p24 vaccine also resulted in marked increase in the antibody response against the gp120 portion of this fusion molecule in comparison to anti-gp120 antibody production in

mice immunized with gp120/p24 vaccine. This could be demonstrated by ELISA with gp120 as solid-phase antigen in which anti-gp120 antibody titer in mice immunized with gp120_{αgal}/p24 was ~30-fold higher than that measured in mice immunized with gp120/p24 vaccine (Figure 15C). These observations strongly suggest that the use of a fusion protein as α-gal vaccine in which only gp120 portion has α-gal epitopes, results in anti-Gal mediated increase in immunogenicity of both gp120 and p24, despite the lack of glycans on p24. The studies with the gp120/p24 fusion protein further suggest that in addition to increasing the immunogenicity of gp120 by converting it into gp120_{αgal}, this envelope glycoprotein of HIV may also serve as an effective platform for targeting to APC other internal virus matrix or core proteins thereby amplifying their immunogenicity.

Figure 15. Studies on gp120/p24 fusion protein as vaccine in anti-Gal producing GT-KO mice. (A) Illustration of fusion of the genes used for production of gp120/p24. (B) Analysis of intracellular staining (ICS) by flow cytometry of IFN γ production in CD8⁺ T cells specific for p24 among splenocytes of mice immunized with gp120_{αgal}/p24 (left panels, mice #1 - #4) and mice immunized with gp120/p24 (right panels, mice #5 - #8). The splenocytes were co-incubated for 6 hours with APC pulsed with p24 peptides. (C) Production of anti-gp120 IgG antibodies in GT-KO mice immunized with gp120_{αgal}/p24 (●), or with gp120/p24 (○), as measured by ELISA with gp120 solid-phase antigen. Mean $\pm$ SD of results from 5 mice per group. From “The natural anti-Gal antibody as foe turned friend in medicine” by U. Galili, 2018, Elsevier/Academic Press, p. 164, after (Abdel-Motal et al. 2010).

Based on the presence of 13-16 complex type glycans on gp120 and the 2-4 antennae on each glycan, it is estimated that glycoengineering of gp120 by the enzymatic reactions described in Figure 1 could result in synthesis of 30-40 α-gal epitopes per molecule. This number of α-gal epitopes is likely to ensure effective immunocomplexing of anti-Gal with the fusion protein and targeting of the fusion α-gal vaccine to APC. This method for generating

fusion proteins between an envelope glycoprotein and a non-glycosylated viral internal protein may serve as a general method for preparation of recombinant vaccinating fusion glycoproteins that elicit effective protective antibody response against envelope glycoproteins and T cell response against both envelope glycoproteins and non-mutating proteins in other viral infections. One example which may be considered is production of influenza virus vaccines containing a fusion protein between HA and the M2 proton channel, since M2 is nearly invariant in all influenza A strains (Fiers et al. 2004; Estrada LD & Schultz-Cherry, 2019). A fusion vaccine of HA_{αgal}/M2 may be protective even against infections with influenza virus in which the HA is mutated, because of the anti-M2 effective immune response due to effective targeting of M2 to APC by the HA_{αgal} portion of such α-gal fusion vaccine. Another plausible example is COVID-19 fusion α-gal vaccines comprised of the S protein envelope glycoprotein of SARS-CoV-2 fused with other envelope or internal proteins and glycoengineering the fusion protein to present multiple α-gal epitopes. Suggested methods for preparation of α-gal SARS-CoV-2 vaccines are discussed in sections below.

SIMILARITIES BETWEEN MOUSE AND HUMAN ANTI-GAL ANTIBODIES

In order to determine whether the studies in GT-KO mice described in this chapter are applicable to humans, it is important to examine the question of similarities between the anti-Gal antibody naturally produced in humans and the anti-Gal antibody elicited in GT-KO mice as a result for several immunizations with wild type pig kidney membrane homogenate. The similarities between human and mouse anti-Gal are as follows:

- *Similarity in anti-Gal titers* – Anti-Gal IgG activity was measured in parallel in human sera and in sera of GT-KO mice immunized with pig kidney membrane homogenate. The analysis was performed by ELISA in which synthetic α-gal epitopes linked to bovine serum albumin (BSA) served as solid phase antigen. Sera from both sources displayed similar anti-Gal binding to α-gal-BSA with half maximum binding at serum dilutions of 1:160-1:320 (Figure 16A) (Abdel-Motal et al. 2006).
- *Binding to glycoengineered vaccine* – Human and mouse anti-Gal were studied for binding to gp120_{αgal} of HIV in order to determine whether both antibodies bind to α-gal epitopes. As shown in Figure 16B, both original recombinant gp120 and gp120_{αgal} display the same size since the replacement of SA on the original gp120 with galactose linked α1-3 to the glycan in gp120_{αgal} does not significantly alter the size of this HIV glycoprotein.

Both human and mouse anti-Gal bind to the α-gal epitopes on gp120_{αgal} but do not bind to glycans on gp120 as demonstrated in Western blot staining with these antibodies (Figure 16B). The presence of α-gal epitopes on gp120_{αgal} but not on gp120 is further validated by binding of the lectin *Bandeiraea simplicifolia* IB4 to the α-gal epitopes on gp120_{αgal} (Abdel-Motal et al. 2006; Wood et al. 1979).

- *Destruction of enveloped viruses by human anti-Gal antibody* – The demonstration of human anti-Gal binding to viral glycoproteins presenting α -gal epitopes is further supported by several studies demonstrating binding of anti-Gal in human serum to a variety of viruses presenting α -gal epitopes and induction of complement dependent virolysis as a result of this binding. Such binding followed by virolysis was demonstrated in Friend Murine Leukemia Virus (Rother et al. 1995), porcine endogenous retrovirus (PERV) (Takeuchi et al. 1996; Hayashi et al. 2004), HIV (Niel et al. 2005), pseudo-rabies virus, rhabdo-, lenti-, and spumaviruses (Takeuchi et al. 1997), Newcastle disease virus, Sindbis virus and vesicular stomatitis virus (Welsh et al. 1998; Pipperger et al. 2020), measles virus (Preece et al. 2002; Dürrbach et al. 2007) and vaccinia virus (Kim et al.). In all these examples, the viruses replicated in cells containing active α 1,3GT, whereas replication of these viruses in human cells lacking α 1,3GT resulted in no binding of human anti-Gal and no virolysis following incubation in human serum.
- *Targeting to APC by human anti-Gal* – The similarity between the GT-KO mouse and human anti-Gal can be further demonstrated by their ability to target anti-Gal immunocomplexed vaccines to APC, such as dendritic cells and macrophages via Fc/Fc receptor interaction. The ability of mouse anti-Gal to mediate such extensive uptake by opsonization was demonstrated above in the studies on OVA-liposomes vaccine (Figure 4). Such targeting was further visualized by the extensive uptake by mouse macrophages of rabbit RBC immunocomplexed with mouse anti-Gal, and no uptake without anti-Gal (LaTemple et al. 1999). The ability of human anti-Gal to opsonize particles and thus perform targeting to APC could be visualized with freshly obtained human lymphoma cells that were glycoengineered to present α -gal epitopes (as in Figure 1). The autologous anti-Gal of the studied patient bound to the glycoengineered lymphoma cells but not to the original lymphoma cells lacking α -gal epitope (Manches et al. 2005). Incubation for 2 hours at 37°C of the original and of glycoengineered lymphoma cells with autologous anti-Gal and with the APC of the patient resulted in extensive uptake of the tumor cells by macrophages and to a lesser extent into dendritic cells, whereas no such uptake was observed with the original lymphoma cells lacking α -gal epitopes (Figure 17). This uptake was inhibited in the presence of anti-CD64 antibody but not by anti-CD32 or anti-CD16 antibodies, implying that the uptake is mediate by high affinity Fc γ I receptors (Manches et al. 2005) which are present also on dendritic cells (Fanger et al. 1996).

All these studies strongly suggest that human anti-Gal and GT-KO mouse anti-Gal display great similarity in their characteristics, including their ability to form immune complexes with vaccinating viruses or virus envelope glycoproteins that are glycoengineered to present multiple α -gal epitopes. Thus, use of α -gal viral vaccines may be further evaluated in studies on safety and efficacy in primate and human trials.

Figure 16. Similarities in activity of GT-KO mouse and human anti-Gal antibodies. (A) Comparison of anti-Gal IgG activity in human sera (●) and sera of mice immunized with pig kidney membrane homogenate (○). Data are of 3 out of 30 humans and 30 GT-KO mice with similar results. (B) Similarity in binding of both antibodies to *do novo* synthesized α -gal epitopes on gp120 by recombinant α 1,3GT. The glycoproteins were subjected to SDS-PAGE electrophoresis followed and Western blotting. Upper gel: Coomassie staining of SDS-PAGE gel. Lower gels: Western blot stained with human anti-Gal, mouse anti-Gal, and the α -gal epitope specific *Bandeiraea simplicifolia* IB4 (BS) lectin. Note that the antibodies and the lectin bind to gp120 $_{\alpha gal}$ and not to gp120. Modified from (Abdel-Motal et al. 2006).

Figure 17. *In vitro* demonstration of anti-Gal mediated uptake of human B lymphoma cells by autologous APC. Human fresh lymphoma cells (B cell lymphoma) were subjected to the reactions in Figure 1 for the synthesis of α -Gal epitopes on the cell surface glycans. Lymphoma cells presenting α -gal epitopes or lacking them (i.e., original cells) were incubated with autologous anti-Gal for 30 min and subsequently, for 2 hours at 37°C with autologous macrophages or dendritic cells. At the end of incubation, the cells were placed on slides and stained. Arrowheads mark nuclei of the APC. Note the uptake of multiple glycoengineered lymphoma cells by the representative macrophage and of one lymphoma cell by the dendritic cell. No uptake of original lymphoma cells lacking α -gal epitopes was observed (x1000). Modified from (Manches et al. 2005).

METHODS FOR INCREASING EFFICACY OF COVID-19 VACCINES BY THEIR ANTI-GAL MEDIATED TARGETING TO APC

While writing this chapter, the world has been coping for 10 months with the COVID-19 pandemic with >35 million known infected individuals and an estimate of >1 million deaths associated with COVID-19 infection. There is an extensive effort for development of prophylactic vaccines against SARS-CoV-2 virus which causes the COVID-19 pandemic. As discussed below, there is a theoretical possibility that presently developed vaccines may be suboptimal for inducing immune protection against SARS-CoV-2 in many elderly individuals. This section discusses possible reasons for suboptimal future vaccine immunogenicity among the elderly and describes methods for converting COVID-19 vaccines into α -gal vaccines, thereby amplifying their immunogenicity.

SARS-CoV-2 is an enveloped, single-stranded, positive-sense RNA virus that belongs to the Coronaviridae family (Zhou et al. 2020.) . The main target for vaccine development against SARS-CoV-2 infection is considered to be the spike (S) protein which is the major envelope glycoprotein of the virus. The notion that S protein may serve as a vaccine has been supported by studies demonstrating both neutralizing anti-S protein antibodies (Cao et al. 2020; Ju et. 2020) and memory T cells specific for the S protein in sera of convalescent

COVID-19 patients (Grifoni et al. 2020; Ni et al. 2020). The S protein is present on the virus envelope as a trimer transmembrane protein that mediates attachment of SARS-CoV-2 to cells, fusion and entry into host cells (Wrapp et al. 2020). The S protein monomer is of the size of ~180 kDa and contains ~1300 aa comprised of two functional subunits. The S1 subunit (~700 aa) mediates viral attachment to its cell surface “docking” receptor, the angiotensin converting enzyme 2 (ACE-2), and the S2 subunit (~600 aa) enables fusion of the virus with the cell membrane and penetration of the virus into the infected cell (Li et al. 2003; Letko et al. 2020; Wan et al. 2020). The S protein has 22 N-glycans forming the glycan shield of SARS-CoV-2. Several of these glycans are of the high mannose type and the rest are of the complex type, as the left glycan in Figure 1.

The two main types of vaccines being developed against COVID-19 are: 1. Vaccines prepared of virus replicating in cell lines, including attenuated viruses, inactivated viruses, split vaccines, subunit vaccines prepared of the virus replicating in cell lines or produced as a recombinant protein in various expression systems, and virus-like particles. 2. Gene based vaccines prepared of nucleic acid (DNA or mRNA) containing the S protein gene. These gene based vaccines introduce the S protein gene into cells of the vaccinated individual and the transfected cells produce the vaccinating S protein which induces the generation of a protective immune response against the virus. The methods discussed in this section for increasing immunogenicity of S protein or of the whole SARS-CoV-2 virus, can be used only with the vaccines generated in the first group. The reason for this limitation is that glycoproteins produced in the vaccinated individual cannot be glycoengineered by the methods discussed below. In contrast, the inactivated whole virus, or the S protein as a subunit vaccine or as a recombinant protein are amenable to glycoengineering of the glycan shield, for converting glycans capped by sialic acid (left chain in Figure 1) into those presenting α -gal epitopes (right chain in Figure 1).

Initial clinical trials with gene base vaccines of SARS-CoV-2 S protein suggest that one vaccine injection does not suffice for inducing significant neutralizing antibody production in vaccinated individuals (Pedro et al. 2020; Jackson et al. 2020). A relatively low immunogenicity may be suggested by the great variability and modest levels of anti-S protein antibody production, observed in COVID-19 patients studied for post symptom detection onset (Xiao et al. 2020; Luchsinger et al. 2020). Taken together with the much higher proportion of elderly patients infected by and dying of COVID-19 compared to young patients (Cobos-Siles et al. 2020; Xie et al. 2020), it is possible that S protein vaccines may require amplification of their immunogenicity in order to increase the range of vaccinated individual benefiting from COVID-19 vaccines. Moreover, the need for providing COVID-19 vaccines worldwide to billions of individuals may require generation of vaccines that elicit a protective immune response with relatively low amounts of vaccinating material, i.e., vaccines with high immunogenicity.

As suggested in the Introduction section, the glycan shield of S protein is likely to negatively affect the immunogenicity of this glycoprotein. Two of the reasons for the low immunogenicity are: 1. The multiple sialic acid units on the glycans on the S protein generate an electrostatic negative charge that surrounds this glycoprotein and thus is likely to induce electrostatic repulsion with the sialic acid units on APC cell membrane glycans. This repulsion decreases the amount of vaccinating S protein molecules internalized by the APC due to random pinocytosis (Figure 2A). 2. The multiple glycans “camouflage” many of the immunogenic peptides of the S protein as they cover ~65% of S protein surface (Walls et al.
